The safety of monosodium glutamates (MSG's) usage has generated much controversy locally and globally. This study investigates the efficacy of *Loranthus micranthus* in modulating the metabolic disorder associated with MSG intake. Thirty five (35) female rats randomized to three groups labeled 1 (7 rats), 2 (21 rats) and 3 (7 rats), respectively were used. They were administered with normal saline, MSG (200 mg/Kg) and MSG (200 mg/kg) + *L. micranthus* (600 mg/Kg), respectively for 28 days. Seven rats were then sacrificed from each group. The remaining rats in group 2 were then redistributed to groups labeled 4 and 5 consisting of 7 rats each. MSG was then withdrawn from all the rats. Group 4 was treated with *L. Micranthus* (600 mg/Kg) while normal saline was administered to group 5. All administrations were carried out for 30 days. The rats were then sacrificed and the serum was used for analysis. Analysis showed increase total cholesterol, triglyceride, low-density lipoprotein (LDL) - cholesterol, glucose and total protein concentrations and a reduced high-density lipoprotein (HDL) - cholesterol (when MSG was administered). These parameters were restored to normal with *L. micranthus* treatment. Although no histological change was observed in the uterus, there was a significant increase in organs relative weight when rats were placed on MSG but this was reversed with *L. micranthus*. The study suggests the efficacy of *L. micranthus* in reversing cardiovascular disorder and its ability to prevent MSG induced fibroid in rat.

Key words: Cardiovascular diseases, cholesterol, Lipid profile, *Loranthus micranthus*, of monosodium glutamates (MSG).

INTRODUCTION

A report by World Health Organization (WHO) indicates that over 80% of the world population still relies on herbs for treatment of diseases and in the past few decades, there has been an increasing demand for medicinal plants
and plant products as alternative to orthodox medicines especially in developing countries (Bright, 2013; WHO, 2008).

Mistletoes are a polyphyletic group of flowering plants comprising over 1300 species from a broad range of habitats across all continents except Antarctica (Nickrent, 2001). They are semiparasitic plants and grow on various host trees and shrubs where they survive by depending on their respective host for mineral nutrition and water, although they produce their own carbohydrates through photosynthesis (Griggs, 1991). Mistletoe was described as “an all-purpose herb” due to its rich traditional uses and it has been widely used in ethnomedicine for various purposes, including antihypertensive, anticancer, antispasmodic, antidiabetic and for treatment of epilepsy, headache, infertility, menopausal syndrome and rheumatism (Moghadamtousi et al., 2013).

Nigeria has wide distribution of mistletoes with different local names that depend on the area where they occur. L. micranthus, a member of the Loranthaceae family is a Nigeria species of the African mistletoe. It grows on various host trees including Persia americana, Baphia nitida, Kola acuminata, Pentaclethra macrophylla, and Azadirachta indica (Osadebe et al., 2012, Moghadamtousi et al., 2013). The plant is widely reputed in folk medicine for its use as antimicrobial, antihypertensive, anticancer, and antidiabetic agent and also for the treatment of headache, infertility, epilepsy, cardiovascular diseases, menopausal syndrome, agglutination, and rheumatism. Some of these ethnomedicinal uses have been supported with scientific data in the literatures (Nkanu et al., 2002; Osadebe and Ukweze; 2004, Grossarth et al., 2007; Orji et al., 2013). Of particular interest to this study is the reported use of the plant among some local people in Nigeria for the management of fibroid [an overgrowth of tissue in the endometrium (inner lining of the uterus)] in women.

Monosodium glutamate (MSG), (2-amino pentane dioic or 2-amino glutaric acid) is the sodium salt of the non-essential amino acid glutamic acid commonly used as a flavor enhancer especially in foods. It is a popular condiment in Nigeria and marketed as Ajinomoto, vflavor enhancer especially in foods. It is a popular essential amino acid glutamic acid commonly used as a flavor enhancer in food (Huthman et al., 2009; Eweka, 2007). As a result, there is a growing apprehension that its excellent bleaching properties could be harmful to the stomach mucosa or worse still inducing terminal diseases in consumers when ingested as a flavor enhancer in food (Huthman et al., 2009; Eweka, 2007). To support this, some authors have reported brain damaging potentials, stunted skeletal development, behavioral aberration, neuro-endocrine disorder, possible learning deficits, seizures (epileptic fits), learned taste aversion and hyperglycemia as possible adverse effects of abuse of the use of MSG (Farombi and Onyema, 2006; Onyema et al., 2006; Ortiz et al., 2006).

Some studies have shown that MSG induces oxidative stress and hepatotoxicity in rats (Onyema et al., 2012; Onyema et al., 2006; Diniz et al., 2004) as well as impaired glucose-induced insulin secretion by pancreatic islets of obese mice (Andreazzi et al., 2009). Another report by Park et al. (2010) proposed that MSG produces altered lipid profile with elevation in reactive oxygen species (ROS) formation and reduction of antioxidant activities. This observation agrees with earlier studies that reported hyperleptinemia (Hollopeter et al., 1998), adiposity and increase of plasma fatty acids and triacylglycerols (Dawson et al., 1997) with oral administration of MSG into rats. Obochi et al. (2009) also reported that MSG administration leads to increased cholesterol, protein and oestrogen which lead to induction of fibroid in rats.

Therefore, the present study was carried out to investigate the efficacy of L. micranthus in preventing or reversing alter plasma lipid profile and cardiovascular disease risk factors associated with MSG administration in rats.

MATERIALS AND METHODS

Monosodium glutamate

MSG was obtained from Sigma Chemical Company Japan. A solution was prepared by dissolving 10 g of MSG in 500 ml distilled water.

Plant authentication and extraction

Fresh leaves of mistletoe were obtained from a farm garden at Odogbolu, Ogun State, Nigeria in August 2013. The plant was identified as L. micranthus at the Botany Department of Olabisi Onabanjo University, Ago-Iwoye, Ogun State. A voucher number EH13510 was thereafter assigned after which specimen was deposited at the herbarium. The leaves were then washed and air dried at room temperature for two weeks. The dried leaves were ground into a powder and 362 grams was soaked in 1000 ml distilled water. The mixture was left to stand for 48 h with occasional stirring. The extracted product was then sieved into a clean container and further concentrated using a rotary evaporator at 40°C. The concentrated product was then lyophilized. The yield of the extract was 8.7%.

Experimental design

Thirty five (35) mature virgin female Wistar rats weighing 155 to
164 g were used in the study. The rats were obtained from the animal house, Department of Physiology, Olabisi Onabanjo University, Ago-Iwoye, Nigeria and were acclimatized for seven days at the Animal Facility Centre, Department of Biochemistry, Olabisi Onabanjo University, Nigeria. All the animals were housed in metallic cages and maintained in well ventilated room provided with 12:12 h light and dark cycle for each 24 h period at a temperature of approximately 25°C. They were all maintained on standard rat pellets and tap water ad libitum throughout the period of the study. All the rats used in the study showed regular estrous cycle length (4 to 5 days). The phases of estrous cycle were determined by observing the vaginal smear in the morning (08:00 h to 10:00 h) according to procedure described previously (Solomon et al., 2010). The animals were initially randomly assigned to three groups labeled as normal control/group 1 (7 rats), test control /group 2 (21 rats) and test group / group 3 (7 rats). Rats in each group were treated as follow: Group 1 (Normal control): administered with normal saline; Group 2 (Test control): administered with MSG (200 mg/kg body weight); Group 3 (Test group): administered with MSG (200 mg/kg b. w) and L. micranthus (600 mg/kg body weight).

All administrations were carried out as a single dose daily for 28 days by oral galvage. After 28 days of administration, seven rats were sacrificed from each group after 12 h fasting; the rats were then evaluated on the basis of preventive effects of L. micranthus. The remaining rats in group 2 were redistributed to two groups of seven rats each, labeled, group 4 (extract treated) and 5 (self-recovery). Administration of MSG was discontinued in the two groups while rats in group 4 were administered with L. micranthus (600 mg/kg) extract; rats in group 5 were treated with normal saline. All administrations were carried out for the next 30 days after which the rats were sacrificed.

All the rats were sacrificed after anesthetia with diethyl ether in a closed jar. Blood was collected by cardiac puncture into plain bottles and the rats were evaluated based on the curative potential of the extract. The uterus, kidney and liver were harvested cleaned of blood and weighed. The uterus was thereafter used for histopathology study.

### Biochemical assay

Initial and the final body weight of all the rats were measured using a Mettler weighing balance (Mettler Toledo Type BD6000, Greifensee, Switzerland). Serum was prepared from the collected blood samples by centrifugation and used for analysis. Fasting blood glucose was measured according to method adopted previously by Miwa et al. (1972) using a glucose kit (enzymatic method) (Sigma). Serum protein determination was by the method of Lowry et al. (1951). Triglyceride was determined using enzymatic colorimetric kits (Wahlefeld, 1974). Both total cholesterol and HDL-C were determined in the serum by the methods previously described (Stein, 1986). From the results, LDL cholesterol was calculated based on the method of Friedewald et al. (1972). According to the method, LDL can be calculated as follows:

\[
LDL = \text{Total cholesterol} - \text{HDL-TG}/5
\]

Atherogenic index was calculated from serum HDL and cholesterol levels using the equation previously reported by Gillies et al. (1986).

\[
\text{Atherogenic index} = \frac{\text{Serum cholesterol level} - \text{serum HDL level}}{\text{Serum HDL level}}
\]

Coronary risk index was obtained by the method of Alladi and Khada (1989).

### Histopathology study

The dissected uterus was immersion-fixed in bunsins fluid over night at room temperature after which the tissues were transferred to ascending grades of alcohol for dehydration. The tissues were cleared with two changes of xylene for one and half hours each, transferred into two changes of molten paraffin wax I and II for one and half hour each and wax- III for overnight in an oven at 65°C for infiltration. The tissue was then processed according to the method previously described (Solomon et al., 2010). The tissue block was serially sectioned at 6 μm thickness using microtome. Strips of sections were gently lowered into the surface of a warm water bath at 40°C. The floated sections were mounted on egg albumin coated microscopical slides, and put in an oven maintained at 60°C for 30 min to fix the tissue firmly on the slide. The slides were dewaxed with two changes of xylene and hydrated with decreasing alcohol concentration and then immersed in water for 5 min. The sectioned tissues were then stained regessively with Ehrlich’s hematoxylin and counter stained with Eosin.

After staining with eosin, tissues were washed in tap water and dehydrated by rinsing in increasing concentration of alcohol and then xylene-I. They were then placed in xylene-II until mounting. Finally, a drop of mountant DPX (A mixture of Distyrene, a Plasticizer, and Xylene) was placed on top of the sections and the cover slip was applied.

### Animal care

The care of the animals was in accordance with the U.S. Public Health Service Guidelines (NRC, 1999) and was approved by the Olabisi Onabanjo University, College of Health Sciences Animal Ethics Com.

### Statistics

All data were expressed as mean ±SEM. One-way analysis of variance (ANOVA) was used to analyze the data. Comparisons between the groups were made at a two-sided alpha level of 0.05. p < 0.05 was considered statistically significant.

### RESULT

Table 1 depicts the variation in serum lipid profile, atherogenic index (AI) and coronary risk index (CRI) with MSG administration and during treatment with L. micranthus. There was a significant increase (p<0.05) in plasma triglyceride, total cholesterol and LDL-cholesterol and a reduction in HDL-cholesterol when MSG was administered. Combined administration of MSG with L. micranthus significantly brought these parameters to the pre-treatment values. Table 1 also indicates that when the rats were treated with L. micranthus for the 30 days after the 28 days of continuous administration of MSG, the observed values of serum triglyceride, total cholesterol, LDL-cholesterol and HDL-cholesterol (96.41±5.93, 120.16±5.93, 41.27±5.15, 26.90±4.02 mg/dl

\[
\text{Coronary risk index (CRI)} = \frac{\text{Total cholesterol}}{\text{HDL- cholesterol}}
\]

\[
\text{Atherogenic index} = \frac{\text{Serum cholesterol level} - \text{serum HDL level}}{\text{Serum HDL level}}
\]

\[
\text{LDL} = \text{Total cholesterol} - \text{HDL-TG}/5
\]

\[
\text{Atherogenic index} = \frac{\text{Serum cholesterol level} - \text{serum HDL level}}{\text{Serum HDL level}}
\]

\[
\text{Coronary risk index} = \frac{\text{Total cholesterol}}{\text{HDL- cholesterol}}
\]

respectively) were not significantly different from the values obtained when MSG and *L. micranthus* were co-administered for 28 days (92.7±3.82, 118.1±5.75, 42.0±5.19, 26.9±4.02 mg/dl respectively). When compared however, the serum lipid of rats that were allowed to recover by itself (without treatment after 28 days administration of MSG) were not different from the observed values prior to withdrawal of MSG. Table 1 also show a significant increase (p<0.05) in atherogenic and coronary risk indexes during MSG administration and when the rats were allowed to recover from MSG administration without treatment (when compared with the normal control values). However, combined administration of MSG and *L. micranthus* and treatment with *L. micranthus* after the initial administration of MSG brought the coronary risk index to the pre-treatment values. Although the atherogenic index values were raised above the normal control level both during combined administration of MSG and *L. micranthus* and when *L. micranthus* was administered after withdrawal of MSG, the observed AI were significantly lowered than the values observed when MSG was administered alone and was also higher than the value that was obtained during the self-recovery process. Administration of MSG significantly increased (p<0.05) the fasting blood glucose above the normal control value (Table 2). Thirty (30) days after withdrawal of MSG without subsequent treatment, the fasting blood glucose level was still observed to be significantly higher (p<0.05) than the normal control value. When MSG was however co-administered with *L. micranthus*, the...

observed fasting blood glucose level of 89.83±2.57 mg/dl was neither different from the normal control value nor was it different from the fasting blood glucose level of 91.67±2.11 mg/dl observed when L. micranthus was administered continuously for 30 days after MSG withdrawal. Similarly, administration of MSG was observed in the study to increase the serum total protein significantly (p<0.05) above the normal control value. The observed serum protein concentration of 24.55±2.80 mg/dl after 28 days of MSG administration was not different from the value of 25.46±3.00 mg/dl observed 30 days after withdrawal of MSG without treatment. Combined administration of MSG and L. micranthus significantly brought the serum protein concentration to the pre-treatment level. When L. micranthus was administered for 30 days after withdrawal of MSG, the serum protein concentration was observed to be lower than the value obtained in the group of rats that were not treated though the observed value was still higher than the value in the normal control group.

Table 3 is the result of the effect of treatment on percentage relative change in kidney, liver and uterus weights. Administration of MSG significantly increased (p<0.05) the percentage relative weight of the uterus, kidney and liver above the normal control value. The same trend was maintained when the weights were monitored 30 days after MSG withdrawal without treatment. The result however showed that combined administration of MSG and L. micranthus and treatment of the rats with L. micranthus for 30 days after MSG withdrawal restored the relative organ weights to the pre-treatment level.

Figures 1 to 5 is the result of the effect of treatment on the histology of endometrium of the uterus. The uterine histology of the control rats showed normal features: single layered columnar epithelial cell with elongated nuclei at the base of the cells, highly folded epithelial lining, numerous and tortuous endometrial glands (Figure 1). No significant alterations were also observed in the histology of all other treatment groups.

DISCUSSION

Iwase et al. (1998) and Suga et al. (1999) has reported that post-natal administration of MSG in rats induces insulin resistance, body weight gain, hyperleptinemia and serum glucose level alteration even though the exact mechanisms for these alterations were not clearly defined. In an effort to find out the exact mechanisms by which MSG predispose to tissue injuries, a study by Onyema et al. (2006) reported that MSG is capable of inducing oxidative stress which leads to hepatotoxicity in rats. Another study with obese mice also reported that MSG may impair insulin secretion by pancreatic islets (Andreazzi et al., 2009). The report from our study confirmed that MSG is capable of causing metabolic alterations in rats. In line with previous study, our study has demonstrated that oral administration of MSG in rats could cause metabolic abnormalities in lipid metabolism which is indicated by marked elevation serum total cholesterol, triglyceride and LDL-cholesterol (hyperlipidemia) with concomitant decrease in plasma HDL-cholesterol level. These observations are in agreement with previous reports by some other authors (Obochi et al., 2009; Pal, 2009; Ogunlabi et al., 2014). This alteration in plasma lipid profile was also reflected in increased atherogenic and coronary risk indices. This is in agreement with report by
Nagata et al. (2006). Our study also shows that both combined administration of MSG and *L. micranthus* and treatment with *L. micranthus* after prolonged exposure to MSG is capable of ameliorating these serum lipid alterations. It has been proposed that MSG elevates reactive oxygen species (ROS) formation and reduction of antioxidant activities (Park et al., 2010) which we opined may be the biochemical basis for the altered lipid profile. Some authors have reported that MSG induces oxidative stress and Reactive Oxygen Species (ROS) production which have been noted play specific roles in the modulation of cellular events (Diniz et al., 2005; Nagata et al., 2006). The ROS react with protein thiol moieties to produce a variety of sulfur oxidations, thus diminishing the insulin receptor signal and inhibiting cellular uptake of triacylglycerol from the blood (Mohamed et al., 2008; Chen et al., 2003). Some studies have linked hypertriglyceridemia to higher serum small dense LDL particles, atherothrombosis and impaired endothelial function, the hallmarks of several prevalent cardiovascular diseases as well as their complications (Lupattelli et al., 2000; Lundman et al., 2001; Ginsberg,
The elevated serum concentration of total cholesterol noted in the rats administered with MSG suggests that MSG predispose to hypercholesterolemia. The increase in the levels of LDL-cholesterol with a simultaneous decreased concentration of HDL-cholesterol reflected that MSG will induce abnormalities in lipoprotein metabolism. Because of the changes in the cholesterol profile and other lipid molecules noted in the present study in the MSG-treated rats, we opined that they may be due to the ability of MSG toxicity to inhibit the activity of hydroxy 3-methylglutaryl-coenzyme. A reductase (HMG-CoA) which plays an important regulatory role in cholesterol biosynthesis, and inhibition of its activity is known to alter the metabolism of all lipids, including cholesterol (Ness and Chambers, 2000). Hypercholesterolemia and abnormalities in lipoprotein metabolism are considered as serious risk factors and important early events in the pathogenesis of atherosclerosis in both peripheral and coronary circulation (Maxfield and Tabas, 2000; Mallick, 2007; Grover-Paez and Omez, 2009). Lipid compounds and products of their oxidation especially LDL accumulate during formation of atherosclerotic lesions (Mallick, 2007).
The LDL functions in the atheroma formation whereas the HDL plays an important role in inhibiting the formation of atheroma (Maxfield and Tabas, 2000; Mallick, 2007). The antiatherosclerotic action of HDL resides in its ability to remove cholesterol from vascular wall, stimulate prostacyclin formation and inhibit the synthesis of adhesive molecules (Pal, 2009). So, lowering the plasma lipid levels through dietary or drug therapy may be beneficial in decreasing the risk of vascular disease.

As regards the ability of L. micranthus to reverse these alterations as reported in this study, we opined, that it is an indication of the efficacy of L. micranthus to prevent predisposition to cardiovascular disease and atherogenesis during MSG intake. Specie of mistletoe, Viscum album was reported in a previous study carried out by Yusuf et al. (2013) to show a dose-dependent relationship for the reducing ability, free radical scavenging and the Fe²⁺ chelating tendency. The study observed that V. album extracts from cola tree compares favorably with the standards agents (ascorbic acid, ethylenediamine tetraacetic acid and buthylated hydroxytoluene used. A phytochemical screening report by Orji et al. (2013) indicated the presence of tannins, flavonoids, saponins, phenols, alkaloids and anthocyanins in the leaves of ethanolic extracts of L. micranthus leaves. A correlation between the total phenol content of plant food and their antioxidant properties has been well reported. This may be the biochemical explanation for the efficacy of L. micranthus leaves extract as reported in this study. Another hypothesis may be that L. micranthus is efficacious in decreasing HMG-CoA reductase activity (an enzyme required for cholesterol synthesis) thereby decreasing the predisposition to increase atherogenic and coronary risk index of MSG (Arari et al., 2000; Lapointe et al., 2006).

The results of our study also show that, administration of MSG to rats induced hyperglycemia which is indicated by elevated level of fasting blood glucose when compared with the normal control rats. Our result corroborates previous report by some other authors who attributed the increase in serum glucose in response to MSG administration to hypertrophy of pancreatic islets with associated hyperinsulinemia, an early marker of insulin resistance, together with impaired glucose uptake by tissues due to the decrease in the number of glucose transporter-4 (GLUT 4) (Seraphim et al., 2001; Diniz et al., 2005; Nagata et al., 2006). Insulin resistance is often associated with clustering of coronary risk factors, which leads to an increased risk of cardiovascular disease, presumably due to promotion of atherosclerosis (Zavaroni et al., 1989; Roberts and Sindhu, 2009). The observed hypertriglyceridemia induced with MSG administration reported in our study may thus be a response to the increased blood glucose level. A positive correlation between hypertriglyceridemia and hyperglycemia induced by MSG has been previously reported (Nayira et al., 2009). The regulation of energy balance is essential to maintain the control of metabolism and body composition (Scharrer, 1999). Importantly, MSG has been widely used to induce obesity through hypothalamic lesions in neonatal period (Nakayama et al., 2003). Though a study by Grassioli et al. (2007) reported glucose disturbances only in neonatal MSG-treated animals compared to adult MSG treatment our study observed elevated fasting blood glucose in adult female rats placed on MSG. For one of the main causes of hyperglycemia in these rats, we opined, it may be related to a decreased amount of GLUT 4 protein found in adipocytes (Macho et al., 2000). It seems true that insulin sensitivity is influenced by the redox state of the organism, whereby oxidative processes may trigger the development of insulin resistance (Evans et al., 2002). Data has been reported to prove that ROS react with protein thiol moieties to produce a variety of sulfur oxida-
tions which attenuates insulin receptor signal and inhibits cellular uptake of triglyceride from blood stream (Chen et al., 2003). This may be the basis for the observed increased plasma triglyceride levels in MSG animals reported in this study.

MSG was also observed in this study to increase the level of total protein. Elevated total protein and cholesterol among some other alterations has been implicated in the induction of fibroid in rats (Obochi et al., 2009). The effect of MSG on protein alteration has been attributed to the activation of transcriptional promoter and enhancer elements used for the control of gene expression which promoted the ability of RNA polymerase to recognize the nucleotide at the initiation stage thereby increasing protein synthesis (Obochi et al., 2009). Our report also shows the efficacy of *L. micranthus* extract to reverse these alterations.

Organ weights are widely accepted in the evaluation of test article-associated toxicities (Black, 2002; Bucci, 2002; Woolley, 2004). In toxicological experiments, comparison of organ weights between treated and untreated groups of animals have conventionally been used to evaluate the toxic effect of the test article and its changes often precede morphological changes. Data from our study indicates that oral administration of MSG predispose to increased relative organ weight of the tissues investigated. This result corroborates previous report by Manal and Nawal (2012) where treatment with MSG was reported to lead to increased liver and kidney relative weight. *L. micranthus* was also observed in this study to be able to restore the relative organ weight in the treated rats to the normal level. When the histopathology of the uterus was however compared, these variations in relative organ weight were not seen to be accompanied with gross morphological changes.

**Conclusion**

In conclusion, MSG was seen to have predisposed to serious biochemical alterations and that both pretreatment with *L. micranthus* and administration of *L. micranthus* subsequent to MSG withdrawal successfully improves these parameters and ameliorates the metabolic alterations caused by MSG administration. Furthermore, *L. micranthus* administration is reported in this study to normalize the MSG induced weight changes in the liver, kidney and uterus of rats.
