The hypoglycemic effects of aqueous leaves extract of *Ocimum gratissimum* was investigated in streptozocin-induced diabetic rats. A single administration of the extract at the doses of 250, 500 and 1000 mg/kg body weight was done. The aqueous extract at the dose of 500 mg/kg significantly lowered blood glucose level (P<0.05) of the diabetic rats by 81.3% after 24 h of extract administration. Preliminary phytochemical screening revealed the presence of reducing sugars, cardiac glycosides, resin, tannins, saponins, glycosides, flavonoids, glycerin and steroids. The median lethal dose (LD₅₀) in rats was calculated to be 1264.9 mg/kg body weight. In conclusion, the leaves extract of *O. gratissimum* possess antidiabetic in streptozocin-induced in diabetic rats.

Key words: *Ocimum gratissimum*, hypoglycemic activity, streptozocin diabetes.

INTRODUCTION

Diabetes is a serious metabolic disorder with micro and macrovascular complications that results in significant morbidity and mortality (Rang et al., 1991). Chronic hyperglycemia during diabetes causes glycation of body protein that in turn leads to secondary complications affecting eyes, kidney, nerves and artery (Sharma, 1993). These may be delayed, lessened or prevented by maintaining blood glucose values close to normal. The increasing number of ageing population, consumption of calories rich diet, obesity and sedentary life style have led to a tremendous increase in number of diabetes world wide. According to WHO projection, the prevalence of diabetes is likely to increase by 35%. Currently there are over 150 millions diabetics world wide and this is likely to increase to 300 million ore more by the year 2025. Statistical projection about India suggests that the number of diabetic will rise from 15 million in 1995 to 57 million in the year 2025 making it the country with the highest number of diabetics in the world (King et al., 1998; Boyle et al., 2001). Therefore it is necessary to look for an urgent solution to manage this problem.

Basil (*Ocimum* spp. L) is a small shrub with many branches, commonly found in many gardens around village huts in Nigeria and planted for its medicinal uses. Originating from Central Africa and South East Asia (Simon and James, 1995), basil is probably one of the most commonly used of all herbs in cooking and there are many recipes – local and foreign that is enhanced by this minty aromatic plant. In Nigeria, about four varieties of basil are known to occur naturally in Southern and Northern part of the country. These are *Ocimum suave*, *Ocimum gratissimum*, *Ocimum basilium* and *Ocimum canum*. Local names of basil in various ethic groups include Efirin (Yoruba), neh-anwu (Ibo), ntion (Efik) and dai-doya ta gida (Hausa). Basil is believed to have significant health benefit. The leaves of African varieties are said to contain thymol oil which is regarded as highly antiseptic and it is also used to prevent mosquito bite (Agnaniet et al., 2005).

Traditionally, basil has been used as a medicinal plant in the treatment of headache, diarrhea, wart, worms and kidney function (Simon and James, 1995; Seung-Jo-Lee et al., 2004). In addition to health benefit, basil is used widely as a condiment or spice and as a source of flavor...
and which may be used in soup preparation. The present study was designed to investigate the hypoglycemic effect of aqueous leaves extracts of *O. grasitimum* in streptozocin-induced diabetes.

**MATERIALS AND METHODS**

**Chemicals**

Streptozocin (STZ) was purchased from Sigma chemicals (St Louis U.S.A). The Biphasic Isophane Insulin AS Mixtard 30 HM Pen fills (Novo Nordisk A/S 2880 Bagsvaerd, Denmark. NAFDAC Reg no 04-1601) was used. ONE TOUCH BASIC meter (Lifescan, Inc 2001 Milpitas, CA 95035, U.S.A.) was used for the determination of blood glucose levels.

**Plant material**

Fresh leaves of *O. grasitimum* were collected from Ahmadu Bello University (ABU) Main campus Zaria in the month January 2007. The plant was identified by Mal. M. Musa at the herbarium unit of Biological Science Department A.B.U., Zaria where a voucher specimen (No. 2637) has been deposited.

**Extract preparation**

The fresh leaves collected were dried under the shade and ground into powder. The powder (5 g) was boiled in 1.5 L of distilled water for 20 min. The extract was cooled, filtered using a filter paper and evaporated to dryness in water bath of 60°C. A brownish residue weighing 15.5 % (w/w) was obtained and kept in air tight bottles in a refrigerator until use.

**Animals**

Wistar strain albino rats of both sexes weighed between 150 - 200 g were obtained from the Animal house, Department of Pharmacology A. B.U., Zaria. The animals were kept and maintained under laboratory condition of temperature, humidity and light. The animals were divided into extract treated groups and the control groups. All the animals were fasted for 12 h, but were allowed free access to water, before commencement of the experiments.

**Phytochemical screening**

The aqueous extracted were subjected to preliminary phytochemical screening test for various constituents. This revealed the presence of reducing sugars, cardiac glycosides, resin, tannins, saponins, glycosides, flavonoids, glycerin and steroids.

**Acute toxicity study**

The lethal doses (LD_{50}) of the plant extract was determined by method of Lorke (1983) using 13 rats. In the first phase, rats were divided into 3 groups of 3 rats each and were treated with the aqueous extract of the plant at doses of 10, 100 and 1000 mg/kg bodyweight intraperitoneal. They were observed for 24 h for signs of toxicity. In the second phase, 4 rats were divided into 4 groups of 1 rat each and were also treated with the aqueous extract at doses of 600, 1000, 1600 and 2900 mg/kg bodyweight (i.p). The median lethal dose (LD_{50}) was calculated using the second phase.

**Induction of diabetes**

Diabetes mellitus was induced by single intraperitoneal dose of 60 mg/kg of streptozocin dissolved in 0.1 m fresh cold citrate buffer pH 4.5 into 12 h-fasted rats. On the third day of STZ-injection, the rats were fasted for 6 h and blood was taken from tail artery of the rats (Burcelin et al., 1995). Rats with moderate diabetes having hyperglycemia (that is, with blood glucose of 250 – 400 mg/dl) were taken for the experiment. The diabetic rats were then divided randomly in the different groups.

**Experimental design**

In the experiment, a total of 25 rats were used, the rats were divided into 5 groups of 5 rats each. Group 1 has normal rats; Groups 2 to 5 have diabetic; Group 2 rats were given Biphasic Isophane insulin 6 i.u/kg, while Groups 3, 4 and 5 were extract treated group at 250, 500 and 1000 mg/kg bodyweight, respectively.

**Determination of blood glucose levels**

All blood samples were collected from the tail artery of the rats at interval. Determination of the blood levels was done by the glucose-oxidase principle (Beach and Turner, 1958) using the ONE TOUCH Basic (lifescan, mulpital CA instrument) and the result were expressed as mg/dl (Rheney and Kirk, 2000).

**Statistical analysis**

Blood glucose levels for each group were expressed in mg/dl as mean ± SEM. The data were statistically analyzed using ANOVA with multiply comparisons versus control group. The values of p<0.05 were considered as significant (Duncan et al., 1997).

**RESULTS**

**Phytochemical analysis**

Freshly prepared extracts were subjected to preliminary phytochemical screening test for various constituents. This revealed the presence of reducing sugars, cardiac glycosides, resin, tannins, saponins, glycosides, flavonoids, glycerin and steroids.

**Acute toxicity study (LD_{50})**

The sign of toxicity were first noticed after 2 – 4 h of extract administration. There was decreased locomotor activity and decreased in sensitivity to touch. Also there was decreased feed intake and prostration after 12 h of extract administration. The median lethal dose (LD_{50}) in rats was calculated to be 1264.9 mg/kg body weight.
of extract administration. The dose of 500 mg/kg was found to be more effective with percentage glycemic change of 80.6 and 81.3% after 8 and 24 h, respectively. The dose of 250 mg/kg, the percentage glycemic change showed an increase after 8 h of extract administration with 5.86% and after 24 h there was a decrease in the percentage (-31.69%) glycemic change.

In regard to the diabetes rats that received 250 and 1000 mg/kg bodyweight of the leave extracts of *O. gratissimum*, there was no significant change in the blood glucose levels compared to the control group. In regard to the dose of 500 mg/kg of *O. gratissimum*, it significantly (P<0.05) lowered the blood glucose level when compared to control after 8 h. After 24 h, there was a significant decrease only in the blood glucose levels of the group treated with 500 mg/Kg body weight of the extract.

### DISCUSSION

Many secondary metabolites participate in a variety of antidiabetic functions *in vivo* (Kako et al., 1997). However, there is paucity of literature on the anti-diabetic potential of this plant. The glycemic change in blood glucose level of diabetic rat at different time intervals after intraperitoneal administration of aqueous leaves extract of *O. grassitimum* at the doses of 250, 500, and 1000 mg/kg is shown in Table 1. In relation to the diabetes rats that received 250 and 1000 mg/kg bodyweight of the leaf extracts of *O. gratissimum*, there was no significant change in the blood glucose levels when compared to the control group. In regard to the dose of 500 mg/kg of *O. gratissimum*, it significantly (P<0.05) lowered the blood glucose level when compared to control after 8 h and 24 h of extract administration. The dose of 500 mg/kg was found to be more effective with percentage glycemic change of 80.6 and 81.3% after 8 and 24 h, respectively. In regard to the dose of 250 mg/kg, the percentage glycemic change showed an increase after 8 h of extract administration with 5.86% and after 24 h there was a decrease in the percentage (-31.69%) glycemic change. Also in relation to the dose of 1000 mg/kg, the percentage glycemic change after 8 h and 24 h of extract administration showed a decreased in the percentage glycemic change of 39.46 and 38.72%, respectively.

In conclusion, the present study showed that aqueous leaves extracts of *O. gratissimum* possessed antidiabetic properties which suggest the presence of biologically active components which may be worth further investigation and elucidation. The effective antidiabetic dose was found to be 500 mg/Kg body weight. Further studies are currently under way to isolate and characterized the active components of the crude extract of this plant.
