**Abstract:**

**Background:** Residents in a rural suburb of Akure jettisoned antibiotic treatment; sought alternative cure to rising incidence of paediatric infections in 2017 from local herbal dealers, with many residents claiming of better treatment response. We investigated these claims since the local herbal formula included kola nut barks and ground termites.

**Methodology:** Microorganisms associated with termite nests on kola nut trees in the affected community were characterized and identified using standard techniques. The Kirby Bauer disk diffusion was used to evaluate the susceptibility of the bacterial isolates to selected antibiotics. Plasmid profile of multiple antibiotic resistant bacterial isolates (MDRIs) was determined by the Birnboim and Doly method while post plasmid curing antibiotic susceptibility was performed on the MDRIs against the same selected antibiotics. The microorganisms were also evaluated for possible antagonistic effects against *Salmonella sp*, *Staphylococcus aureus* and *Streptococcus pyogenes* isolated from paediatric patients during the period of study using previously described methods.

**Results:** Bacteria (*Corynebacterium sp*, *Streptococcus sp*, *Acinetobacter sp* and *Lactobacillus sp*) and fungal (*Geotrichum condidum*, *Aspergillus niger*, *Fusarium oxysporum* and *Fusarium fujikuroi*) were isolated from the termite nests. The antibiotic susceptibility revealed that *Corynebacterium sp* and *Streptococcus sp* were multiply antibiotic resistant, and this was confirmed to be plasmid mediated based on plasmid analysis and curing. The *Lactobacillus sp*, *Aspergillus niger*, *Fusarium fujikuroi* and *Geotrichum condidum* exhibited mild antagonisms against *Staphylococcus aureus*, *Salmonella sp* and *Streptococcus pyogenes* isolated from paediatric patients.

**Conclusion:** This study suggests that termite nests on kola nut trees contain microbes that possess antagonistic actions against pathogens from paediatric patients and that some bacteria associated with termite guts may pose significant risk of increased antibiotic resistance if implicated in human infections.

**Keywords:** Termite nests, Resistance, Antagonistic microbes, Termites, Plasmid, Kola nut tree

Abstrait:

Méthodologie: Les micro-organismes associés nids de termites sur les arbres de noix de kola dans la communauté affectée ont été caractérisés et identifiés à l’aide de techniques standard. La diffusion sur disque de Kirby Bauer a été utilisée pour évaluer la sensibilité des isolats bactériens aux antibiotiques sélectionnés. Le profil plasmidique de plusieurs isolats bactériens résistants aux antibiotiques (MDRI) a été déterminé par la méthode de Birnboim et Doly tandis qu’une sensibilité aux antibiotiques après polymérisation du plasmid a été réalisée sur les MDRI contre les mêmes antibiotiques sélectionnés. Les micro-organismes ont également été évalués pour d’éventuels effets antagonistes contre Salmonella sp, Staphylococcus aureus et Streptococcus pyogenes isolés de patients pédiatrick pendant la période d’étude en utilisant les méthodes décrites précédemment.

Résultats: Des bactéries (Corynebacterium sp, Streptococcus sp, Acinetobacter sp et Lactobacillus sp) et fongiques (Geotrichum condidum, Aspergillus niger, Fusarium oxysporum et Fusarium fujikuroi) ont été isolées des nids de termites. La sensibilité aux antibiotiques a révélé que Corynebacterium sp et Streptococcus sp étaient multi-résistants aux antibiotiques, et cela a été confirmé comme étant médicamenteux par les plasmides sur la base de l’analyse et du durcissement des plasmides. Les Lactobacillus sp, Aspergillus niger, Fusarium fujikuroi et Geotrichum condidum présentaient de légers antagonismes contre Staphylococcus aureus, Salmonella sp et Streptococcus pyogenes isolés de patients pédiatriques.

Conclusion: Cette étude suggère que les nids de termites sur les arbres de noix de kola contiennent des microbes qui possèdent des actions antagonistes contre les agents pathogènes des patients pédiatrick et que certaines bactéries associées aux intestins des termites peuvent poser un risque significatif d’augmentation de la résistance aux antibiotiques si elles sont impliquées dans des infections humaines.

Mots-clés: nids de termites, résistance, microbes antagonistes, termites, plasmidique, arbre à noix de Kola

Introduction:

Termites are social insects that live in enclaves known as termite nests or “termitaria” (1,2). They belong to the order Isoptera with more than 1800 species in 200 genera (3,4). They form their nests using mud, gut exudates, secretions and faeces (5,6). In various rural settlements of western Nigeria, the termite species Odontotermes badius is predominant and serves as food supplement for local residents (6). Certain bacteria form part of termite gut flora and aid the digestion of food in termite guts (1,2). However, fungi are also present in termite guts either through ingestion of infested food or propagating fungal spores (1,5). Conversely, studies have recently linked interactions existing between termites and microorganisms inhabiting their guts with respect to the tree environment on which they live (1,6). This has necessitated investigation into the termite microbiota and the types of microbes associated with their nests (3,4).

Kola nuts (Cola sp) are widely cultivated in West Africa because they serve as natural stimulants that suppress fatigue (7). In Western Nigeria, the species, C. nitida is widely cultivated in various farm settlements for various purposes and this tree species harbor vast reserves of termites, since kola nut is an excellent source of soft wood (7).

Our field correspondence with local residents in a suburb of Akure, Nigeria in 2017 revealed that due to rising incidence of paediatric infections, the inhabitants jettisoned known antibiotics and sought alternative medical help from local herbal concoction dealers, with claims of better treatment response from the use of these concoctions in affected infants. These claims from use of local medicinal formula which included kola nut barks and ground termites were widely uncorroborated scientifically. In view of this, our study sought to identify microorganisms from termite nests on kola nut trees in the affected community, evaluate possible antagonistic effects of these microbes against clinical isolates of paediatric importance, and raise public health awareness of associated risks with use of these herbal concoctions.

Materials and methods:

Description of study location

The study area is Ipogun, a very small community with dispersed settlements. It is a
suburb of Akure metropolis, Nigeria at 7°11´N 7°12´N/ 5°4´ E 5°9´ E coordinates (8).

Sample collection and processing

We designated kola nut plantations in the study area as sampling points for sample collection in September 2017. A total 20 dead termite aggregate samples from termite nests on kola nut trees in the study location were collected using guidelines described by Barreto et al., (9). The samples were stored under airtight ice packs and analyzed microbiologically within 4hrs of collection (10).

Isolation of microorganisms from prepared samples

Sample preparation and isolation of microorganisms was according to Afolami et al. (1). Sterile normal saline was used as diluent and 1.0g of sample stocks was weighed into 1.0ml of the diluent for a serial dilution process and four dilutions were obtained for a pour plate technique. Thereafter, 1ml of the last dilution was used to inoculate already prepared nutrient agar and potato dextrose agar plates containing 250mg chloramphenicol (for total filamentous fungi count). Bacterial cultures were incubated at 37°C for 24hrs and fungi at 26±2°C for 3-5 days (1,2).

Identification of bacterial isolates

Identification of bacterial isolates was done using methods of Afolami et al., (1) and Aribisala et al., (2). Subcultures of distinct colonies were identified by gram reaction and biochemical tests such as catalase, motility, sugar fermentation (glucose, sucrose, lactose and mannitol), triple sugar iron, methyl red/voges proskauer test, oxidase and spore staining tests. The identified isolates were freshly subcultured on MacConkey and Bile Esculin agar plates, and incubated at 37°C for 24hours (11).

Identification of fungi isolates

The authors used methods described in Samson et al., (12) and Onifade et al., (13) for identification of fungi isolates and compared the cultural and microscopic characteristics of fungal mycelia with the available literature using the Compendiums for Air, Soil, Food and Indoor fungi (12,13). The cultural and micro-morphological properties of isolated fungi were obtained through microscopy of stained mycelia with cotton blue in Lactophenol dye (13). Photomicrographs of different mycelium clones were juxtaposed with matching information contained in the available literature for air and soil fungi as described in Onifade et al., (13).

Antibiotic susceptibility of bacterial isolates

The Kirby Bauer disk diffusion test was used to evaluate invitro activity of selected antibiotics against the bacterial isolates on Mueller Hinton (MH) agar. An 18h old broth culture of each isolate was standardized with 0.5McFarland standards and plated on MH agar using sterile swabs as previously described (14). The selected antibiotic disks (AB Biodisk, Solna, Sweden) from seven different antibiotic classes used were amoxicillin (25μg), erythromycin (15μg), ofloxacin (5μg), ciprofloxacin (5μg), pefloxacin (5μg), cotrimoxazole (25μg), ceftriaxone (30μg), gentamycin (10μg), streptomycin (10μg) and chloramphenicol (15μg).

The antibiotic disks were gently placed on the plates and incubated for 24hours at 37°C. The diameter of zone of inhibition of each isolate was measured with a calibrated ruler and interpreted as sensitive, intermediate or resistant according to the guidelines of the National Committee for Clinical Laboratory Standards (15) while Staphylococcus aureus ATCC 25923 was used as control strain. Test isolates with resistance to more than two classes of antibiotics were designated as multiple antibiotics resistant (14, 16).

Plasmid profile analysis of MDRIs

Plasmid extraction and analysis from the multiple antibiotic resistant bacterial isolates (MDRIs) was carried out using alkaline lysis method (Zymogen, UK) as previously described by Akingbade et al., (16). Plasmid extraction solution containing 20.0mM sodium acetate and 2.0mM EDTA adjusted to pH 7.8 using 10% acetic acid was prepared with a sample buffer containing 25% sucrose, 5.0mM sodium acetate and 0.05% bromophenol blue. Electrophoresis of plasmid DNA was done on 0.9% agarose gel stained with gr-Green dye (1μl/ml) at room temperature while pBR322 DNA/BsuRI (HaeIII) was used as marker. After the run time, gel was observed under UV transillumination and analyzed using a photo documentation system.

Plasmid curing of MDRIs

The curing of resistant plasmids from the MDRIs was done overnight by using the methods of Birnboim and Dolly (17) and Vivyan et al., (11). Antibiotic susceptibility testing of MDRIs post-plasmid curing was carried out with the same set of antibiotic disks (AB Biodisk, Solna, Sweden).
Antagonistic assays
All the isolates (bacteria/fungi) were evaluated for possible antagonistic effects against clinical pathogens (*Salmonella* sp, *Staphylococcus aureus* and *Streptococcus pyogenes*) isolated from paediatric patients and obtained from the Department of Laboratory Services, Ondo State Specialist Hospital, Akure, Nigeria. These pathogens were adjudged to have had direct impact on the rising incidence of paediatric infections in Akure suburbs at the time of the research.

The Fokkema and Heuvel (18) method was used in evaluating antagonistic potentials of fungal isolates while the methods described by Afolami et al., (1) and Aribisala et al., (2) were used to evaluate antagonistic potentials of bacterial isolates against the clinical pathogens. The susceptibility cutoffs in the assays were determined by susceptible-dose-dependent criteria of the 2012 Clinical and Laboratory Standards Institute (19) and as described by Jabeen et al., (20). The inhibition zones were denoted as positive (+ve) at ≥16.00mm, intermediate (I) at 11.00-15.00 mm and negative (-ve) at ≤10.00mm (1,27). *Candida parapsilosis* ATCC 49247 and *Haemophilus influenzae* ATCC 22019 were used as control strains in the antagonistic assays.

Data analysis
The diameters of zone of inhibition for the antagonistic assays were obtained by means of triplicate values and separated using Duncan’s New Multiple Range test at p < 0.05 level of significance (and 95% confidence interval) to determine whether they were significant or not.

Results:

The bacterial isolates across sampling points are shown in Tables 1 and 2. A total of forty-three bacteria isolates; *Corynebacterium* sp (n=9), *Lactobacillus* sp (n=17), *Acinetobacter* sp (n=10) and *Streptococcus* sp (n=7), and 22 fungi isolates; *Aspergillus niger* (n=8), *Fusarium oxysporum* (n=6), *Fusarium fujikuroi* (n=5) and *Geotrichum condidum* (n=3) were recovered from the samples.

The highest zone diameter of inhibition to antibiotics by the bacterial isolates was 20.35±1.28mm while the lowest zone was 3.20±1.08mm. The susceptibility patterns of the isolates are denoted as susceptible (S), resistant (R) and intermediate (I) in Tables 3 - 6. As shown in Table 3, two of the four bacteria genera/species (*Corynebacterium* sp, and *Streptococcus* sp) were multiple antibiotic resistant isolates (resistant to more than two classes of antibiotics tested). A representative isolate from each genus was profiled for plasmid analysis as shown in Fig 1.

The antagonistic features (inhibitory effects) of the bacterial isolates against the pathogens obtained from paediatric patients (*Salmonella* sp, *Staphylococcus aureus*, and *Streptococcus pyogenes*) are shown in Table 4 while the antagonistic features (inhibitory effects) of the fungi isolates against these pathogens are shown in Table 5. Only *Lactobacillus* sp among the bacterial isolates had mild antagonism against the pathogens with inhibition zone ranging from 12.82±1.68 to 16.19±1.21mm, while the fungi (*Fusarium fujikuroi* and *Geotrichum condidum*) had antagonistic activity against the pathogens with inhibition zones ranging from 11.91±1.66 to 18.91±1.33mm.

The zones of inhibition and susceptibility patterns of the MDR isolates after plasmid curing in Table 6 showed the two MDR bacteria genera (*Corynebacterium* sp, and *Streptococcus* sp) to be susceptible, which confirms that their multidrug resistance property was plasmid mediated.

Discussion:

The microorganisms identified from this study showed that termite nests have high microbial diversity. Some of the organisms obtained in this study such as **Corynebacterium** sp, **Acinetobacter** sp, **Streptococcus** sp, **Aspergillus niger** and **Geotrichum candidum** have been investigated in studies on termite nest microflora, most especially by Afolami et al., (1) and Aribisala et al., (2) where authors recently embarked on a similar work. Fungi isolates obtained in this study such as **Fusarium oxysporum** and **Aspergillus niger** produce mycotoxins which are of pathological importance to kola nut trees and termites alike, although recent reports by Afolami et al., (1) and Aribisala et al., (2) may suggest that these fungi would also directly impact economic losses and effects on crop plants, animals and humans.

A previous report by Bignell et al., (21) suggested that termites may harbor micro-aerophilic bacteria that aid cellulose digestion and this underscores the benefit the mutualistic relationship between termites and bacteria inhabiting their guts. Our study underscored this claim since the bacteria **Acinetobacter** sp and **Corynebacterium** sp obtained from the study are micro-aerophilic (5). The study by Lo and Eggleton (22) also affirmed that termites use faecal matter to make internal ventilating structures (combs) which act as substrates for the growth of the symbiotic fungi in their nests. This corroborates the presence of soil borne fungi, A. niger, F. oxysporum, F. fujikuroi and G. candidum obtained from our study.

Earlier reports by Afolami et al., (1) and Aribisala et al., (2) observed that termites might develop defensive strategies against invading pathogens by producing antimicrobial substances in defensive glandular secretions which allow them resist termite borne pathogens over an extensive period of time. It might be safe to suggest that these previous reports explain why all the bacterial isolates obtained from termite nests have varying degrees of antibiotic resistance since they may have been exposed previously to wide range antimicrobial substances from termite secretions and insecticide sprays prior to this study. This may also partly give a scientific explanation to uncorroborated claims made by local respondents about the potency of termite based herbal concoction in treating paediatric infections. However, the results also presented showed that these locally made herbal
Microbial antagonistic effects of kola nut termite nests against pathogens

Concoctions used by local dwellers may pose serious health risks since bacteria in this study showed stellar multiple antibiotic resistance and respondents risk ingestion of these MDRIs. Consequently, the susceptibility patterns of the bacteria isolates observed in our study might have resulted from exposure of termite nests on kola nut barks to active components in many herbicides used by local farmers, which may be similar to the compounds present in the antibiotics used in our study. This may trigger a form of acquired antibiotic resistance in the isolates. Similar observations have been made by Brune and Dietrich (23), Afolami et al., (1) and Arisibala et al., (2). As observed in our study, plasmid-mediated antibiotic resistance mechanisms might have been responsible for resistance in the MDRIs, which could manifest as antibiotic efflux, gene mutation, and aberrant protein expressions that reduce permeability of bacteria cell envelopes to many antibiotics, resulting in resistance (24).

Local residents from Ipogun community have described clinical symptoms suggestive of acute typhoid fever and infantile food poisoning in children, attributed to Salmonella sp, S. aureus and S. pyogenes (personal communication). Meanwhile, similar infection patterns caused by pathogens used in our study have also been previously reported by the local health authorities of the affected area, which informed the testing of isolates we obtained from termite tubes in our study against these pathogens. Rabasa et al., (25) described the clinical presentations of acute salmonellosis in infants as a case study in western Nigeria (same region of the affected community) while Shittu et al., (26) and Odigwe et al., (27) suggested that infants (below age 9) may be more susceptible to haemolytic infections and food poisoning in Nigerian communities where basic life amenities are inadequate. Rural communities such as Ipogun (the study area) lack basic amenities. Hence, it is not surprising that the rising incidence of paediatric infections in this community had defied antibiotic interventions. This explains why the local residents affected sought for traditional indigenous medical interventions.

Since this study aims at corroborating claims made by local residents, the authors cited the report of Holt and Leepage (4) suggesting that microorganisms inhabiting the termite guts are capable of exhibiting overt antagonisms against other pathogens as part of their adaptation. Hence, Lactobacillus sp, F. fujikuroi and G. condidum showed mild antagonism against the pathogens tested. The antagonisms exhibited by Lactobacillus sp may be due to the production of antimicrobials such as bacteriocins and lactic acid derivatives that can hinder the metabolism of the pathogens, while the fungal isolates (F. fujikuroi and G. condidum) are producers of lytic enzymes and toxic exudates that can lyse cell walls of pathogens (24).

Although previous reports by Afolami et al., (1) and Arisibala et al., (2) described antagonistic patterns of isolated organisms from Mango and Cocoa trees in Ibule-soro, the findings presented in this current study showed antagonisms of Lactobacillus sp and certain fungi (F. fujikuroi and G. condidum) from termite nests on kola nut trees in a different community (Ipogun). This made the current study better defined in scope for a new study area than previous studies. Hence, the antagonisms observed in this study clearly establish termite tubes to contain certain microbes that may aid inhibitory properties of the local medicine formula adopted by rural dwellers in this affected community against pathogens causing infantile infections in their community.

Conclusion:

This study has shown that Lactobacillus sp and certain fungi contained in termite nests on kola nut trees possess antagonistic potentials against pathogens obtained from paediatric patients and that some bacteria present in termite guts may possess overt multiple drug resistances due to their carriage of resistant plasmids.

Acknowledgements:

The authors acknowledge the immense contributions of Mr. Babajide Ajayi of the Department of Microbiology, Federal University of Technology Akure, Ondo state, Nigeria during the course of this research.

Conflict of interest/source of fund:

There are no conflicts of interests and the authors received no funding from any organization or persons for the research.
