Abstract:

Background: Pseudomonas species are responsible for different healthcare-associated infections and are inherently resistant to many commonly used antibiotics. Hospital antibiograms are either absent or not regularly available in most healthcare facilities in Nigeria. The objective of this study is to present the antibiogram of Pseudomonas isolates in Federal Teaching Hospital Gombe (FTHG) in order to guide antibiotic prescription for better patient safety in the hospital.

Methodology: The is a hospital-based cross-sectional study. A total of 4309 bacterial isolates were recovered from aerobic cultures of routine clinical specimens including urine, sputum, blood, swabs, aspirates, biopsies, seminal fluids and cerebrospinal fluids at the Medical Microbiology laboratory of the hospital between January and December 2019. Pseudomonas species were identified by colony morphology, Gram-reaction and conventional biochemical tests. Antibiotic susceptibility testing was performed on each Pseudomonas isolate using the modified Kirby-Bauer disk diffusion method on Mueller-Hinton agar and results interpreted according to the guideline of the Clinical and Laboratory Standards Institute (CLSI). Data were analysed using the Statistical Package for Social Sciences (SPSS™) software version 23.0.

Results: Of the total 4309 bacterial isolates, 436 (10.1%) Pseudomonas species were identified, with majority (49.8%) from urine specimens. Antibiotic susceptibility test results revealed average susceptibility rates of 73.8%, 70.1%, 66.2%, 59.5%, and 34.3% to ciprofloxacin, gentamicin, levofloxacin ceftazidime, and carbencillin respectively. These rates fluctuate only slightly for each of the antibiotic during the 12 months period of survey.

Conclusion: Pseudomonas species were most sensitive to ciprofloxacin and gentamicin among the first line antibiotics in FTHG in 2019. Regular updates and presentation of hospital antibiogram especially for intrinsically resistant bacteria such as Pseudomonas involved in healthcare associated infections, is an important tool in combating antimicrobial resistance and ensuring patient safety.

Keywords: antibiogram, Pseudomonas, antimicrobial resistance, antimicrobial stewardship, patient safety

Antibiogramme des espèces de Pseudomonas: un outil important pour lutter contre la résistance aux antibiotiques pour la sécurité des patients à Gombe, Nigéria

1Département de microbiologie médicale et d’immunologie, Université d’État de Gombe/ Hôpital d’enseignement fédéral, Gombe, Nigéria
Abstrait:

Contexte: Les espèces de *Pseudomonas* sont responsables de différentes infections associées aux soins de santé et sont intrinsèquement résistantes à de nombreux antibiotiques couramment utilisés. Les antibiogrammes hospitaliers sont absents ou ne sont pas régulièrement disponibles dans la plupart des établissements de santé au Nigéria. L’objectif de cette étude est de présenter l’antibiogramme des isolats de *Pseudomonas* dans l’Hôpital Universitaire Fédéral de Gombe (FTHG) afin d’orienter la prescription d’antibiotiques pour une meilleure sécurité des patients à l’hôpital.

Résultats: Sur les 4309 isolats bactériens au total, 436 (10,1%) espèces de *Pseudomonas* ont été identifiées, la majorité (49,8%) à partir d’échantillons d’urine. Les résultats des tests de sensibilité aux antibiotiques ont révélé des taux moyens de sensibilité respectivement de 73,8%, 70,1%, 66,2%, 59,5% et 34,3% à la ciprofloxacine, à la gentamicine, à la lévofloxacine ceftazidime et à la carbénicilline. Ces taux ne fluctuent que légèrement pour chacun des antibiotiques au cours de la période de 12 mois d’enquête.

Conclusion: Les espèces de *Pseudomonas* étaient les plus sensibles à la ciprofloxacine et à la gentamicine parmi les antibiotiques de première intention dans le FTHG en 2019. Les mises à jour régulières et la présentation de l’antibiogramme hospitalier, en particulier pour les bactéries intrinsèquement résistantes telles que *Pseudomonas* impliquées dans les infections associées aux soins, sont un outil important dans la lutte contre la résistance aux antimicrobiens et assurer la sécurité des patients.

Mots clés: antibiogramme, *Pseudomonas*, résistance aux antimicrobiens, gestion des antimicrobiens, sécurité des patients

Introduction:

*Pseudomonas* are non-fermentative oxidase-positive, motile, aerobic Gram-negative rods belonging to the family *Pseudomonadaceae*, with a large genome of approximately 6.3 million base pairs (Mb), encoding 5567 genes (1). *Pseudomonas* commonly colonizes hospital environment, equipment, and have remained a prominent cause of healthcare-associated infections (HAIs) (2). They typically cause diseases in immunocompromised individuals but occasionally infects immunocompetent hosts, and are often associated with ventilator-associated pneumonia (VAP), central line-associated bloodstream infection (CLABSI), surgical site infection (SSI), respiratory infections in cystic fibrosis (CF) patients, and catherer-associated urinary tract infections (CAUTI) (3,4).

*Pseudomonas* generally possesses several virulence factors including lipopolysaccharide, type IV pili, type III and VI secretion systems, alginate, exotoxin A, proteases, quorum sensing, generation of oxidative stress in the airways, formation of biofilm and pigments (1). *Pseudomonas* generally are intrinsically resistant to several antibiotics, and recently, more resistance from acquired sources is progressively increasing (5).

Antibiogram is a summary of the periodic susceptibility pattern of organisms isolated within a specific area which is regularly communicated to the hospital community to guide appropriate use of antimicrobials and empirical treatment of infections (6), while patient safety is a health care discipline that focuses more on preventing, controlling, and minimizing risks, harm, and errors in healthcare (7). Patient safety together with antimicrobial stewardship and infection prevention and control (IPC) constitutes the major pillars of an integrated approach to health systems strengthening (7).

Inappropriate use of antimicrobials is the main driving force in the development of resistance by microorganisms, and these resistant organisms pose significant threat to patient safety globally (8). Antibiotic classically promote optimal use of antimicrobials by encouraging a targeted approach, thereby reducing treatment-related cost and also minimizing or slowing the development of antimicrobial resistance leading to improved quality of life and patient safety (7).

Studies specifically on *Pseudomonas* antibiogram are few in this part of the country. Communication and dissemination of information regarding the antibiotic susceptibility pattern of local isolates is critical for appropriate antimicrobial prescribing and infection control in healthcare.

**Introduction**

*Pseudomonas* are non-fermentative oxidase-positive, motile, aerobic Gram-negative rods belonging to the family *Pseudomonadaceae*, with a large genome of approximately 6.3 million base pairs (Mb), encoding 5567 genes (1). *Pseudomonas* commonly colonizes hospital environment, equipment, and have remained a prominent cause of healthcare-associated infections (HAIs) (2). They typically cause diseases in immunocompromised individuals but occasionally infects immunocompetent hosts, and are often associated with ventilator-associated pneumonia (VAP), central line-associated bloodstream infection (CLABSI), surgical site infection (SSI), respiratory infections in cystic fibrosis (CF) patients, and catherer-associated urinary tract infections (CAUTI) (3,4).

*Pseudomonas* generally possesses several virulence factors including lipopolysaccharide, type IV pili, type III and VI secretion systems, alginate, exotoxin A, proteases, quorum sensing, generation of oxidative stress in the airways, formation of biofilm and pigments (1). *Pseudomonas* generally are intrinsically resistant to several antibiotics, and recently, more resistance from acquired sources is progressively increasing (5).

Antibiogram is a summary of the periodic susceptibility pattern of organisms isolated within a specific area which is regularly communicated to the hospital community to guide appropriate use of antimicrobials and empirical treatment of infections (6), while patient safety is a health care discipline that focuses more on preventing, controlling, and minimizing risks, harm, and errors in healthcare (7). Patient safety together with antimicrobial stewardship and infection prevention and control (IPC) constitutes the major pillars of an integrated approach to health systems strengthening (7).

Inappropriate use of antimicrobials is the main driving force in the development of resistance by microorganisms, and these resistant organisms pose significant threat to patient safety globally (8). Antibiotic classically promote optimal use of antimicrobials by encouraging a targeted approach, thereby reducing treatment-related cost and also minimizing or slowing the development of antimicrobial resistance leading to improved quality of life and patient safety (7).

Studies specifically on *Pseudomonas* antibiogram are few in this part of the country. Communication and dissemination of
Antibiotic outcomes to health care workers, hospital community, and globally on regular basis, is also lacking. In this study, we present the FTHG 2019 *Pseudomonas* antibiogram, which is aimed at providing a guide for the empirical antibiotic prescribing practices among physicians to combat antimicrobial resistance for better patient safety.

**Materials and method:**

**Study setting and ethical approval**

This is a hospital-based cross-sectional study carried out in FTHG, a 457 beded tertiary hospital in north-eastern Nigeria. The hospital has a functional IPC programme and multidisciplinary patient safety team (MPST). Ethical approval for this study was obtained from the research and ethics committee of FTHG.

**Identification and antibiotic susceptibility of *Pseudomonas* specie isolates**

All *Pseudomonas* isolates recovered from clinical specimens (urine, sputum, blood, swabs, aspirates, biopsies, and seminal fluids) received and processed from at the Medical Microbiology laboratory of FTHG from January to December 2019, were included. Identification of *Pseudomonas* species was manually done using conventional methods including colonial morphology, Gram stain reaction, oxidase and motility tests.

**In vitro** susceptibility testing of the isolates to five commonest first-line anti- *Pseudomonas* antibiotics in our facility was performed by the modified Kirby-Bauer disk diffusion method on Mueller-Hinton agar using single antibiotic disks (ceftazidime 30µg, gentamicin 10µg, ciprofloxacin 5µg, levofloxacin 5µg and carbenicillin 100µg) (Oxoid, UK). The zone diameter of inhibition (measured in millimetres) for each isolate was interpreted as sensitive or resistant using the guidelines of the Clinical and Laboratory Standards Institute (CLSI) for *Pseudomonas* (9).

**Data analysis**

Data were analysed using the Statistical Package for Social Sciences (SPSS™) software version 23.0.

**Results:**

Of the total 4309 bacterial isolates recovered from clinical specimens in 2019 at the Medical Microbiology laboratory of FTHG, *Pseudomonas* species were 436 (10.1%), about half (49.8%) of which were isolated from urine specimens while others were as shown in Table 1. The monthly distribution and percentage antibiotic susceptibility of the *Pseudomonas* species are highlighted in Table 2.

The average sensitivity rates of *Pseudomonas* species against commonly used antibiotics in our facility were 73.8% (ciprofloxacin), 70.1% (gentamicin), 66.2% (levofloxacin), 59.5% (ceftazidime) and 34% (carbenicillin) (Fig 1).

**Discussion:**

*Pseudomonas* species are organisms with a remarkable propensity to develop resistance to a wide range of antibiotics more commonly in hospital settings. It has inherent resistance to many commonly used antibiotics thereby making it a frequent agent responsible for inappropriate empirical antibiotic therapy which is associated with increased healthcare burden. Poor prescribing practices have been identified as a major driver in the development of resistance against antibiotics with *Pseudomonas* being very prominent.

This study revealed a relatively high prevalence of *Pseudomonas* (10.1%) among other bacterial isolates recovered from clinical specimens in Gombe, which is similar to 9.7% reported by Dash et al., (10) in Peshawar, but higher than 5.1% reported in Nepal (11). This further highlights the significance of this pathogen and the importance of having an antibiogram to guide empiric antibiotic prescription especially given its inherent resistance to many commonly used drugs in the treatment of bacterial infections.

About half of the isolated *Pseudomonas* were from urine specimen which conforms to the findings by Shrestha et al., (11) and probably because urine is also the most common specimen received in our laboratory during the period Miscellaneous specimens such as swabs and aspirates usually from skin and soft tissue infections (SSTIs) and surgical site infection (SSIs) were very common sources of *Pseudomonas* isolates in our study, and similar to the findings of Dash et al., (12) in South Odisha, India.

The *in vitro* susceptibility of *Pseudomonas* to ciprofloxacin was high at 73.8% average in this study, which was a similar

CIP = Ciprofloxacin, LEV = Levofloxacin, CAZ = Ceftazidime, CN = Gentamicin, CAR = Carbenicillin

Fig 1: Average percentage sensitivity and resistance of Pseudomonas to first-line antimicrobials

- The susceptibility to gentamicin was also relatively high, similar to that reported by Shrestha et al.,(11). The 59.6% susceptibility rate to ceftazidime (a third generation cephalosporin) reported in this study is similar to the rate reported by Gill et al., (14) and Iregbu et al., (15). A study in Saudi Arabia by Rashid et al.,(16) reported 70.0% sensitivity of Pseudomonas to levofloxacin, which is similar to 66.2% reported by us, as against a higher resistance rate 36.1% reported by Dash et al.,(12).
- Carbenicillin, a carboxypenicillin used in the treatment of Pseudomonas infections, showed little in vitro efficacy as only 34.3% of the Pseudomonas isolates were sensitive to it.
in our study, similar to a study conducted by Jazani et al., in Iran with 35% sensitivity rate. This high resistance rate may be due to the increasing transfer of beta-lactamase genes between Pseudomonas species and members of the family Enterobacteriaceae (17).

The monthly susceptibility rates show very little variations of Pseudomonas isolates to each of the 5 commonly used anti-Pseudomonas antibiotics in our facility. These antibiogram results were discussed monthly and annually presented to the hospital community at the instance of the MPST, outlining the trend of infection, susceptibility, and resistant patterns of Pseudomonas species to guide and improve antibiotic prescribing practices.

**Conclusion:**

Antibiogram remains an important tool in combating AMR through improved prescribing practices at all levels of healthcare delivery. Pseudomonas are among the common clinically important bacterial isolates in Gombe and most commonly recovered from urine and swabs/aspirates associated with healthcare-associated urinary tract and skin/soft tissue infections. Among the first line antibiotics at FTHG in 2019, Pseudomonas were most sensitive to ciprofloxacin and least sensitive to carbencillin.
