ABSTRACT

Body odour caused by bacterial growth is of great concern to those affected. To ameliorate this, deodorants, which are substances applied to avert body odour, are designed and used. These deodorants are claimed to have antibacterial activities. This work was therefore, carried out to determine the antibacterial activities of the deodorants marketed in Owerri municipality. Owerri is the capital of Imo State of Nigeria. To determine this, twenty (20) deodorants from ten (10) different manufacturers made up of fourteen (14) roll-on and six (6) sprays were assessed using punch-hole plate diffusion technique on nutrient agar plates. The deodorants were purchased from Ekeonunwa market, New market, Relief market, and some supper markets, all in Owerri Municipality. These deodorants were tested against Laboratory isolates of Staphylococcus epidermidis, Pseudomonas aeruginosa, Escherichia coli and Proteus mirabilis obtained from Federal Medical Centre (FMC) and Modesty Medical Laboratory Owerri and reconfirmed using morphological and biochemical tests. Out of the twenty (20) deodorants tested, 18 (90%) were active against the organisms, 17 (85%) were active against Staphylococcus epidermidis, 15 (75%) against P. mirabilis, 11 (55%) against E. coli and 10 (50%) against P. aeruginosa. It was also observed that deodorants “roll - on” were more active 14 (100%) than the deodorants “sprays” 4 (66.6%). From this study, it was observed that the deodorants tested had antibacterial activities.

Key words: Deodorants, Antibacterial, body, odor
INTRODUCTION

Deodorants are substances applied to the body to affect body odour caused by bacteria growth and the smell associated with bacterial breakdown of perspiration in armpits, feet and other body areas. A sub group of deodorants, ‘antiperspirants’, affect odour as well as prevent sweating by affecting sweat glands. Antiperspirants are typically applied to the underarms, while deodorants may also be applied on the feet and other areas in the form of body sprays.

Human perspiration is largely odourless until it is fermented by bacteria that thrives in hot, humid environments. The human underarm is among the most consistently warm areas on the surface of the human body, and sweat glands provide moisture, which when excreted, has a vital cooling effect. When adult armpits are washed with alkaline soap, the skin loses its acid mantle, raising the skin pH and disrupting the skin barrier. Many bacteria thrive in this elevated pH environment. These bacteria feed on the sweat from the apocrine glands and on dead skin and hair cells, releasing hydrogen ions and lactic acid that is the primary cause of body odour. Underarm hair wicks the moisture away from the skin and aids in keeping the skin dry enough to prevent or diminish bacterial colonization. The hair is less susceptible to bacterial growth and therefore is ideal for preventing the bacterial odour. While deodorants, reduce body odour by killing the odour causing bacteria, they do not affect the amount of perspiration the body produces. Antiperspirants, on the other hand inhibit the activity of sweat glands, so less moisture is produced in addition to avoiding unpleasant wetness. These products also decrease odour because there are less sweat for the bacteria to act upon.

The terms ‘deodorants’ and “antiperspirants” are often used interchangeably, although they describe two different products. While the most frequent active ingredient in commercial antiperspirants is Aluminium chloride and Aluminium zirconium tetrachlorohydryl gly, deodorants are usually alcohol-based, containing some antimicrobial agents such as Fernesole, triclosan, Paraben, Zinc riconolate, triethyl citrate, chlorophyllin copper complex and other metal, chalent compounds that slow bacterial growth.

Deodorants exhibit their antimicrobial activities, by reducing the body pH which in turn inhibits the growth of microorganisms that produce malodour. Another difference between deodorants and antiperspirants is that, while deodorants are considered to be cosmetics products because they only control odour, antiperspirants are actually drugs because they affect the physiology of the body. The first ever deodorant was produced by zingal in the 9th Century in Al-Andalus. Ever since then modernizations have been going on, with some criticisms from the US food and Drug Administration (FDA) and Environmental protections Agency (EPA) which brought about what we now have in the market as present day deodorants.

Deodorants and antiperspirants come in many forms. What is commonly used, varies from country to country. In Europe, aerosol sprays are popular, as are cream and roll-on forms. In the United States, solid or gel forms are dominant. And in Nigeria (especially Owerri), both the sprays and the roll-on brands are common. Many people use and believe in the antibacterial effectiveness of these deodorants, which they hope will prevent or reduce the body odour.

This work therefore, was carried out to determine the antibacterial effect of these deodorants marketed in Owerri, the capital of Imo State of Nigeria.

It is also aimed at comparing the level/degree of efficacy between the two brands marketed in Owerri.

MATERIALS AND METHODS

ORGANISM

The organisms used were laboratory isolates such as Staphylococcus epidermis, (skin normal flora) Proteus mirabilis, Pseudomonas aeruginosa and Escherichia coli which were obtained from Federal Medical Center Owerri (FMC) and Modesty Medical Laboratory Owerri in Imo State of Nigeria from June – November 2011. The organisms were tested, using standard discs and were found to have zones of inhibition of more than 15 mm diameter against pencillin, ampicillin, gentamycin and ampicillin respectively.

These isolates were reconfirmed before being used in this research work. The reconfirmation was done in Modesty Medical Laboratory following the conventional method of identification such as Morphological, Grams staining reaction technique, Motility and Biochemical methods.

PREPARATION OF DEODORANT

A total of twenty (20) deodorants from ten (10) different manufacturers were tested. They were made up of fourteen roll-ons (R1-R14) and six sprays (S1-S6). The deodorants were selected randomly. The fluid of each deodorant roll-on, was aspirated aseptically into sterile tubes.

While that of the spray was sprayed into a sterile container before been used for this work.

SUSCEPTIBILITY TESTING

Plate diffusion technique using the punch-hole method was adopted, oxidid nutrient agar medium which was used was prepared and sterilized according to the manufacturer’s instruction. The nutrient agar plates were inoculated with bacteria each plate for each bacterium but was done in duplicate.

The plates were inoculated with the organism after dilution to give about 10⁶ cells/ml. Punch holes were made using sterile cock borers of 10mm diameter. Each hole was labelled against the deodorant and filled, allowed to stay for about 30 minutes before incubation at 37°C for 18 hours. Zones of inhibition were measured using mm ruler. Any deodorant giving an inhibition zone of more than 2 mm on either side of the hole was regarded as having antibacterial activity.

RESULTS

The antibacterial activities of twenty (20) deodorants from ten (10) different manufacturers consisting of fourteen (14) roll-ons and six (6) sprays were assessed using agar diffusion
brands marketed in Owerri.

This work aimed primarily to determine the antibacterial activity against *Staphylococcus epidermidis*, *Proteus mirabilis*, *Escherichia coli* and *Pseudomonas aeruginosa*. Diameter of the zones of inhibition was measured. Zones less than 2mm on either sides of the hole were considered resistant.

Out of the twenty (20) deodorants that were tested against the organisms, 18 (90%) have zones of inhibition greater than 2mm on each side. Seventeen 17 (85%) showed antibacterial activity against *S. epidermidis*, fifteen 15 (75%) inhibited *P. mirabilis*. Eleven 11 (55%) was active against *E. coli* and 10 (50%) inhibited *P. aeruginosa*.

All the deodorants that were active against *S. epidermidis* showed zones of inhibition above 5mm, except R4, R14, S1 and S2 that had 2mm zones of inhibition each and R11 showed the highest zone of inhibition (15mm) against *S. epidermidis.*

*P. aeruginosa* was the least sensitive of all the organisms to the deodorants, 10 (50%). Out of the ten deodorants that were active against it, R9 and R10 showed the highest zone of inhibition 13mm each.

Among the fourteen (14) roll-on deodorants assessed, eleven 11 (78.6%) showed zones of inhibition against all the organisms, fourteen 14 (100%) were active against *S. epidermidis*, ten 10 (71.4%) against *P. aeruginosa*, Eleven 11 (78.6%) against *E. coli* and fourteen 14 (100%) against *P. mirabilis*. Comparing the six (6) spray deodorants assessed, none (0%) was active against all the organisms, but 3 (50%) were active against *S. Epidermidis*, two 2 (33.3%) against *P. mirabilis*. None (0%) was active against *P. aeruginosa*, and *E. coli*.

**DISCUSSION**

This work aimed primarily to determine the antibacterial activities of different brands of deodorants marketed in Owerri metropolis of Imo State, Nigeria, as well as comparing the level/degree of efficacy between the two brands marketed in Owerri.

The deodorants roll-on, R13, R8, and R10 were discovered to have higher level of activity to all the four tested organisms with ([15,8,10,15], (14,13,15,14), and (13,13,13,12)) mm diameter respectively. This peculiar high levels of zones of inhibition reveals the antibacterial efficacies of their various active ingredients (such as triclosan, fanesole, paraben, triethyl citrate and so on). Such level of antimicrobial activity is desirable in the production of deodorants, and possession of acceptable level of antimicrobial activity by super critical Hops extract have been used as natural deodorants.

R4, R13, and R14 on the other hand showed no zone of inhibition to some of the organisms ([2,0,0,4] (9,0,0,6) and (2,0,0,2)) mm diameter respectively. This could mean that their various active ingredients are contained in low concentrations. This is proven by the statement that some bacterial species can develop low level resistance to triclosan at its low bacteriostatic concentrations due to Fable mutations which results in a decrease to triclosan’s effect on ENR-NAD + binding.

Considering sprays, only four sprays (S4, S2, S5, S9) showed zones of inhibition to some of the organisms and among the four sprays that showed the zones of inhibition, only S5 showed appreciable zone of 6mm diameter to two of the organisms, others showed zones less than 3mm diameter each to one of the organisms only. This may be attributed to the fact that their various active ingredients are contained in very low concentration, regardless of the fact that they were listed on the containers of the sprays in their right proportions. This is in agreement with who stated that ‘Another way for these bacteria to gain low-level resistance to triclosan is to over express fable because some bacteria have innate resistance to triclosan at low bacteriostatic level.

Again, the proportion of the ingredients may be in their right order, but, because they are in their gaseous states, they do not have long time of contact with the organisms before they evaporate, thereby bringing the concentration in contact with the organism lower than what it should be. This is also in agreement with.

Then, looking at the susceptibilities of the test organisms used, the high level of susceptibility shown by *Staphylococcus epidermidis* (85%) could be related to the fact the organism is a normal flora of the skin which is the primary target of deodorants production. *Staphylococcus* along side with *Corynebacterium* and *Propionibacterium* were listed as the notable bacterial skin normal flora.

*Pseudomonas aeruginosa* showed the lowest susceptibility (50%) to all the deodorants tested. Some of deodorants tested were found to have (0%) activeness against it. This could be because *P. aeruginosa* posses multi-drug efflux that pumps triclosan out of the cells.

**CONCLUSION AND RECOMMENDATIONS**

In conclusion, we confirm that Deodorants in Owerri market are active against bacterial growths associated with breakdown of perspiration in armpits, feet, and other areas of the body to produce body odour.

We therefore recommend the use of deodorants to control the body odour caused by bacterial breakdown of lipid and protein in sweat, especially during the Adolescent and adult stages of life, when the apocrine gland is developed and produces sweat rich in protein and fatty acid.

We also recommend to the manufacturers, that enough active ingredients be added in the production of different brands of deodorants to enable them achieve their primary aim of production.

Finally we recommend that the National Agency for Food and Drug Administration and Control (NAFDAC) and the Consumers Protection Council (CPC) should rise up to their responsibility of ensuring that the ingredient listed on the containers of these deodorants and their concentrations are actually corresponding to their real contents to avoid deceiving the poor masses. Also further monitoring researches be done on this aspect.
