ABSTRACT

Most of biochemical reactions in the body generates Reactive Oxygen Species (ROS) which are involved in the pathogenesis of oxidative stress-related disorders like diabetes, nephrotoxicity, cancer, cardiovascular disorders, inflammation and neurological disorders. Antioxidants are used to protect the cells or tissues against potential attack by ROS. Most medicinal plants possess a rich source of antioxidants such as flavonoids, phenols, tannins, alkaloids among others. These phytochemicals are currently pursued as an alternative and complimentary drug. The study was carried out to determine Pharmacognostic, antioxidant and acute toxicity of Vitellaria paradoxa root and stem bark. The Vitellaria paradoxa was extracted with water and methanol, screened for their phytochemical properties and antioxidant effects. Chemo-microscopical studies revealed the presence of cellulose cell wall, lignin, calcium oxalate crystals, tannins, starch and mucilage while calcium carbonate was absent in the stem bark but present in the root. The average moisture contents were 7.30% and 6.80% in stem bark and root respectively. The water and ethanol/alcohol extractives were 24.0% and 20.0% for stem bark while 25.50% and 19.0% for the root respectively. Alkaloid, flavonoids, saponins, tannins, steroids, triterpenes, carbohydrate and phenols were detected in both aqueous and methanol extracts while anthraquinones was absent in all the extracts. The DPPH radical scavenging ability of the extract showed the following trend Ascorbic acid > Stem bark extract> Root extract. Toxicity of the samples was expressed as LD$_{50}$; it was found above 5000 mg/kg and did not cause mortality in all the tested rats. These results suggested that Vitellaria paradoxa root and stem bark have moderate antioxidant potentials. Further study is necessary for isolation and characterization of active antioxidant agents which can be used to treat various oxidative stress related diseases. Keywords: Antioxidant, Acute toxicity, DPPH, Phytochemical, Pharmacognostic, Vitellaria paradoxa,
Stress-related disorders have become epidemic in developing and under-developed countries. Conventional therapeutic strategies mostly attempt to relieve the clinical manifestations of these disorders and their complications. However, studies have shown they tend to increase toxicity leading to damage of sensitive organs like liver and brain, they are also suspected to be mutagenic (Krishnasamy, 2013). Against this backdrop, the popularity of the taste, but lowered or reduced the chewing have a very pleasant taste, washing improves the physiochemical properties of the gum of *Vitellaria paradoxa* is aimed at evaluating the phytochemical and antioxidants therapies are now widely practiced in most of the developing countries (Mohan et al., 2013).

*Vitellaria paradoxa* belongs to the family sapotaceae it is commonly known as shea tree, shi tree, *Vitellaria* or Karite. The local names in Hausa are dan ka’raye, k’awara, ka’danya, mai ka’da’i or mai ka’ danya, while in Yoruba it is called aku malapa, emi-emi and in Igbo it is called okwuma (Hall et al., 1996). It is an indigenous plant to West Africa occurring in Mali, Cameroon, Cote d’ivoire, Ghana, Guinea Togo, Nigeria, Sudan, Senegal and Ethiopia (Okollu et al., 2004), Burkina Faso and Uganda (Lovett and Haq 2000). *Vitellaria paradoxa* gum obtained from the latex of *Vitellaria* when dried can be used as a chewing gum base, but it does not have a very pleasant taste, washing improves the taste, but lowered or reduced the chewing quality of the gum (Hall et al., 1996). This work is aimed at evaluating the phytochemical and physiochemical properties of the gum of *Vitellaria paradoxa* so as to determine its suitability as a pharmaceutical excipient.

Despite the fact that the root and stem bark of *Vitellaria paradoxa* have several medicinal properties, no standardization parameter has been assessed. Due to lack of standard parameters, proper identification and ascertaining quality and purity of the root and stem bark of *Vitellaria paradoxa* in the events of adulteration has been thwarted. Since antioxidants hold a key in preventing oxidative stress-related disorders, many plant extracts and their secondary metabolites are being explored for their antioxidants effects (Gomathi et al., 2013). The use of plant based antioxidants, plays an important role in preventing activation of the oxidation induced signaling pathways in our bodies (Joseph et al., 2002). Therefore, the identification of the antioxidants activities of stem bark and root extracts of *Vitellaria paradoxa* are important step in increasing our understanding about their usage in treatment of various stress-related disorders.

**MATERIALS AND METHODS**

**Collection and Identification of Plant Materials**
The fresh *Vitellaria paradoxa* stem bark and root was collected from local farms around Babura, Jigawa State, Nigeria. Samples from the plant were taken to the Herbarium unit of the Department of Plant Biology, Bayero University, Kano, Nigeria for authentication. The voucher specimen was deposited at the Herbarium with a reference code BUKHAN649.

The collected stem bark and root of *Vitellaria paradoxa* were washed and dried at room temperature in the laboratory for one week. Samples were ground to powder using a mortar and pestle. The powdered plant samples were kept in polythene bags until extraction.

**Chemo-microscopic Studies on the Stem of *Vitellaria paradoxa***
Powdered sample (stem bark and root) of *Vitellaria paradoxa* was used for this study to detect the presence of cell wall materials and cell inclusions. Finely ground sample of plant was cleared in a test tube containing 70% chloral hydrate solution. It was then be boiled on a water bath for about thirty minutes to remove obscuring materials. The cleared sample was mounted with dilute glycerol onto a microscope slide. Using various detecting reagents the presence of cell wall materials and cell inclusions was detected in accordance to WHO (2011) guidelines.

**Determination of Cell wall Materials**

**Test for Cellulose**
A drop or two of iodinated zinc chloride was added to the powdered sample and allowed to stand for a few minutes and observed under a microscope. It stained cellulose cell wall blue to blue- violet.

**Test for Lignin**
The powdered plant material was moistened on a slide with a small volume of phloroglucinol and allowed to stand for about two minutes or until almost dry. A drop of hydrochloric acid was added and view under a microscope. Pink stained or cherry red was observed, for the presence of lignin (WHO, 2011).

**Test for Suberized or Cuticular cell walls**
A drop or two of Sudan red was added to the cleared powdered sample and allowed to stand for few minutes and observed under a microscope. Orange red or red colour was observed presence of suberin or cutin on the cell.

**Test for Gum and Mucilage**
To a small portion of the cleared powdered sample of the plant, a drop of ruthenium red was added. Appearance of pink coloration was considered positive for gums and mucilage.
Determination of Cell Inclusions/ Cell Contents

Test for Starch grains
To a small portion of the cleared powdered sample of the plant, N/50 iodine was added. Appearance of blue-black or reddish-blue coloration on some grains would be considered positive for starch.

Test for Calcium oxalates and Calcium Carbonates
To a small portion of the cleared powdered sample of the plant, HCl was added, dissolution of crystals in the powdered drug without effervescence was considered positive for calcium oxalate while slow dissolution with effervescence was considered positive for calcium carbonate.

Inulin
A drop of 1-naphthol and that of sulphuric acid was added to the powdered sample and viewed under the microscope. Spherical aggregations of crystals of inulin turned brownish red and dissolve.

Test for Tannins
To a small portion of the cleared powdered sample of the plant, 5% ferric chloride solution was added. Appearance of greenish black colour was considered as positive for tannins.

Extraction of Plant Materials
Powdered stem bark and root (50g) of *Vitellaria paradoxa* were separately extracted with distilled water (500 ml) followed by methanol (500 ml) for 72 hours each using cold maceration. The extract obtained were concentrated using water bath, allowed to evaporate and stored in desiccator for further use.

Determination of Physicochemical Parameters of the Powdered Stem bark and Root
Some physicochemical parameters of the powdered sample of the plant such as moisture content, total ash, acid-insoluble ash, water-soluble ash, alcohol and water extractive values were determined (WHO, 2011).

Moisture Content
3 g each of the powdered sample was accurately weighed and placed in some clean, dried evaporating dishes of known weights. They were placed in an oven and heated at a temperature of 105°C for 1 hour, then cooled in a desiccator and re-weighed. Heating and weighing were repeated until a constant weight was obtained. The weight loss on drying was computed following the formula below:

\[
\text{Percentage Moisture content} = \frac{\text{Initial Weight of Powder} - \text{Final Weight of Powder}}{\text{Initial Weight of Powder}} \times 100
\]

Total Ash Value
2g of powdered plant materials was accurately weighed and placed separately in a crucible of known weight. It was heated gently and the heat gradually increased until it is white indicating the absence of carbon. It was allowed to cool in a desiccator and weighed; this was repeated until a constant weight was obtained. The total ash value was determined as a percentage with the formula below:

\[
\text{Percentage Ash Value} = \frac{\text{Weight of Residual Ash}}{\text{Original Weight of Powder}} \times 100
\]

Acid-insoluble ash
This was determined for the powdered plant material. 25ml of dilute hydrochloric acid was added to the crucible containing ash. It was covered with a watch glass and gently boiled for 5 mins. The watch glass was rinsed with 5ml of hot water and the liquid added to the crucible. The insoluble matter was collected on an ashless filter-paper and washed with hot water until the filtrate is neutral. The filter-paper containing the insoluble matter was transferred to the original crucible, dried in an oven and ignited to a constant weight. The residue was allowed to cool in a suitable desiccator for 30 minutes and then weighed without delay (Evans, 2009).

The acid-insoluble ash will then be calculated as a percentage for each of the two plants with the formula

\[
\text{Percentage Acid insoluble Ash} = \frac{\text{Weight of Residual Ash}}{\text{Original Weight of Powder}} \times 100\%
\]

Water soluble ash
To the crucible containing the total ash, 25ml of water was added and boiled for 5 minutes. The insoluble matter was collected in a sintered glass crucible. It was then be washed with hot water and ignited in a crucible for 15 minutes at 105°C. The weight of the residue was subtracted from the weight of the total ash. The content of water soluble ash per air dried powdered sample was calculated and recorded (WHO, 2011).

Alcohol-Soluble Extractive Value
4g of each of the plant material was separately weighed in a conical flask. 100ml of ethanol was added and macerated for 24 hours, during which the mixture was frequently shaken within the first 6 hours using a mechanical shaker. It was filtered and 25ml of the filtrate transferred into an evaporating dish of known weight and evaporated to dryness on a water bath. It was dried to a constant weight, the percentage of alcohol-soluble extractive value was then determined for the plant as
Percentage Ethanol Extractive Value = \( \frac{\text{Weight of Extract in 25ml} \times X}{\text{Original Weight of Powder}} \times 100\% \)

**Water-Soluble Extractive Value**
Same procedure as in alcohol-soluble extractive value was repeated here for the sample, but solvent for extraction here was water.

Percentage Water Extractive Value = \( \frac{\text{Weight of Extract in 25ml} \times X}{\text{Original Weight of Powder}} \times 100\% \)

**Preparation of Plant extracts**
Fifty (50g) of the powdered stem bark and root were soaked in 500ml of methanol and distilled water. The mixture were allowed to stand for 3 days at room temperature (28 ±2ºC) with hourly agitations. Each extract was sieved through a muslin cloth, filtered through a Whatman (No.1) filter paper, poured unto a clean evaporating dish and placed on a water bath at 50°C until all the solvent evaporated.

**Qualitative Phytochemical screening of Vitellaria paradoxa Stem bark and Root extracts**
The plant extracts were subjected to phytochemical screening in order to identify the phytochemical constituents of the plant using the method described below.

**Tests for carbohydrates**

*Molish’s (General) Test for Carbohydrates*
To 1 ml of the extract, 1 ml of Molish’s reagent was added in a test tube, followed by 1 ml of concentrated sulphuric acid down the test tube to form a lower layer. A reddish colour at the interfacial ring indicates the presence of carbohydrate (Evans, 2009).

**Tests for Saponins**

*Frothing test*
About 10ml of distilled water was added to a portion of the extract and was shaken vigorously for 30 seconds. The tube was allowed to stand in a vertical position and was observed for 30 mins. A honeycomb froth that persists for 10-15 mins indicates presence of saponins (Evans, 2009).

**Tests for Flavonoids**

*Shinoda Test*
A portion of the extract was dissolved into 1-2 ml of 50% methanol in the presence of heated metallic magnesium chips and few drops of concentrated hydrochloric acid were added. Appearance of red color indicates presence of flavonoids (Evans, 2009).

**Tests for Alkaloids**

*Wagner’s Test*
Few drops of Wagner’s reagents were added to a portion of the extract, whitish precipitate indicates the presence of alkaloids (Evans, 2009).

**Test for Steroids and Triterpenes**

*Liebermann-Burchard’s test:*
Equal volume of acetic anhydride were added to the portion of the extract and mixed gently. Concentrated sulphuric acid (1 ml) was added down the side of the test tube to form a lower layer. A colour change observed immediately and later indicates the presence of steroid and triterpenes. Red, pink or purple colour indicates the presence of triterpenes while blue or blue green indicates steroids (Evans, 2009).

**Test for Cardiac Glycosides**

*Kella-killiani’s test:*
A portion of the extract was dissolved in 1 ml of glacial acetic acid containing traces of ferric chloride solution. This was then transferred into a dry test tube and 1 ml of concentrated sulphuric acid was added down the side of the test tube to form a lower layer at the bottom. Interphase for purple-brown ring was carefully observed, this indicates the presence of deoxy sugars and pale green colour in the upper acetic acid layer indicates the presence of cardiac glycosides (Evans, 2009).

**Test for Tannins**

*Ferric chloride test:*
Exactly 3-5 drops of ferric chloride solution was added to the portion of the extract. A greenish black precipitate indicates presence of condensed tannins while hydrolysable tannins give a blue or brownish blue precipitate (Evans, 2009).

**Test for Anthraquinones**

*Borntrager’s test:*
Exactly 5ml of chloroform was added to the portion of the extract in a dry test tube and shaken for at least 5 mins. This was filtered and the filtrate shaken with equal volume of 10% ammonium solution, bright pink colour in the aqueous upper layer indicates the presence of free anthraquinones (Evans, 2009).

**Antioxidant activity Procedure**
The antioxidant activity of the plant extracts was measured in terms of radical scavenging ability, using a stable radical 2,2-diphenyl-1-picrylhydrazyl (DPPH) according to the modified method adopted from (Sani and Dailami, 2015). 200µl of 100µM methanol solution of DPPH were added to 100µL of various concentrations of the sample fractions in methanol (1000, 500, 250, 125, 62.5, 31.25, 15.63 and 7.8µg/ml) and made to react in dark for 30 mins time at room temperature. Absorbance of the blank, test and control were recorded at 517 nm. The experiment was performed in triplicate and scavenging activity was calculated by using the following formula and expressed as percentage of inhibition.
Inhibition = \frac{\text{Absorbance of control}}{\text{Absorbance of test}} \times 100\%

The concentration corresponding to the 50% inhibition (IC_{50}) was determined using probit analysis by means of SPSS 16.0 software. The IC_{50} values obtained are compared with that of ascorbic acid as a standard antioxidant.

**Acute toxicity studies of methanolic extract of Vitellaria paradoxa Stem bark and Root**

**Lethal Dose (LD_{50}) Determination**

The method of Lorke (1983) was employed for this test. Thus, the phase I involved the oral administration of three different doses of 10, 100 and 1,000 mg/kg of the crude extract, to three different groups of three adult wister albino rats. In the fourth group, three adult male wister albino rats were administered with equivalent/volume of distilled water to serve as control. All the animals were orally administered the extract using a curved needle to which a catheter had been fixed. The animals were monitored closely every 30 minutes for the first 3 hours after administration of the crude extract and hourly for the next 6 hours for any adverse effects. Then the animals were left for 72 hours for further observation.

When no death occurred, the phase II was employed, only one animal was required in each group. Groups 1–4, animals were orally given 1,500, 2,200, 3,250 and 5,000 mg/kg dose levels of the crude extract. All the animals were left for observation as in stage one.

**RESULTS**

Chemo-microscopical studies on the powdered stem bark and root of *Vitellaria paradoxa* were found to have cellulose cell wall, lignin, calcium oxalate crystals, tannins, starch and mucilage while calcium carbonate was absent in the powdered stem bark but present in the root.

The result of average moisture contents using loss on drying method was calculated to be 7.30% and 6.80% in stem bark and root respectively. The percentage yield of total ash, acid insoluble and water soluble matter were recorded in percentage values as 7.20%, 3.21% and 6.10% respectively in powdered stem bark while 8.70%, 3.90% and 6.20% in the powdered root. The water and ethanol/alcohol extractives obtained were 24.0% and 20.0% for stem while 25.50% and 19.0% for the root respectively.

The percentage yield of different extracts (Table 3) showed aqueous had the highest yield (12.4 % and 14.4 %) in both stem bark and root respectively.
Alkaloid, flavonoids, saponins, tannins, steroids, triterpenes, carbohydrate and phenols were detected in both aqueous and methanol extracts while anthraquinones was absent in all the extracts. Cardiac glycoside was detected in both aqueous and methanolic root extract but absent in the stem bark extract.

The antioxidant activity of the methanol stem bark and root extracts of *Vitellaria paradoxa* and ascorbic acid used as control were used found to be dose dependent. The higher the dose of the extracts, the lower the absorbance and consequently the higher the percentage inhibition of the free radicals.

No death was recorded in the first phase of the study in rats. In the second phase, doses of 1500mg/kg, 2250mg/kg, 3250mg/kg and 5000mg/kg were used and no death was also recorded. The oral median lethal dose (LD$_{50}$) for the methanol stem bark and root extract of *Vitellaria paradoxa* was therefore estimated to be greater than 5000mg/kg and no sign of behavioural changes were also observed.
DISCUSSION

Chemo-microscopical features of powdered stem bark and root of *Vitellaria paradoxa* revealed the presence of cellulose cell wall, lignified cell wall, mucilage, tannins, starch, suberin and calcium oxalate crystals while calcium carbonates were found to be absent. The microscopic structures are most valuable in the identification of powdered drug as their identification is largely based on the form, the presence or absence of certain cell types and cell inclusions (Jeremiah et al., 2019). The physicochemical parameters including the moisture content, acid insoluble ash, water soluble ash, alcohol extractives value, water extractives and total ash values were determined from the powdered parts of the plant (Jeremiah et al., 2019). These are values that are very important as basis to judge the identity, purity and in detecting adulterants in a crude drug (Jeremiah et al., 2019). Moisture content (5.53 %) was not high which indicated less chances of microbial degradation of the drug during storage. The general requirement of moisture content in crude drug is recommended not to be more than 14 % British Herbal Pharmacopoeia B.H.P (1990). The value obtained in this research work was within the accepted range. Determination of the moisture content helps preventing degradation of drug during storage. The lower the value, the less likelihood of degradation of drug and suggests better stability of the product. Moisture is considered an adulterant because of its added weight as well as the fact that excess of moisture promotes mold and bacterial growth (Jeremiah et al., 2019). Total ash value represents both the physiological and non-physiological ash from the plant. The non-physiological ash is an indication of inorganic residues after the plant drug is incinerated. The acid insoluble ash values (3.21 % and 3.9 %) obtained in this study indicated that the plant was in good physiological condition and contained little extraneous matter such as sand, silica and soil. The total ash value is used as criteria to judge the identity and purity of drugs (Jeremiah et al., 2019).

Extractive value is determined when a given amount of plant material is extracted with a particular solvent. When the crude drug is extracted with a particular solvent, it produces a solution that contains several constituents (Jeremiah et al., 2019). The nature of the crude drug and the solvent used determines the constitution of the phyto-constituents present (Jeremiah et al., 2019). It also helps to determine if the crude drug is debilitated or not (Jeremiah et al., 2019). This study indicated that ethanol gave lower extractive value (20.0% and 19.0 % w/w) compared to water which had extractive value of 24.0% and 25.5 % w/w in stem bark and root respectively. The antioxidant activity of the plant (stem and root) determined (Table 7) were expressed in terms of IC$_{50}$ value. *Vitellaria paradoxa* was found to possess lower DPPH scavenging activity compared to the standard drug. However, the scavenging ability of the stem bark extracts are higher than that of the root extracts. Moreover, smaller IC$_{50}$ values means better scavenging activity/antioxidant potential and higher IC$_{50}$ value, indicate lower activity (Cesur et al., 2017). This indicate that the *Vitellaria paradoxa* extracts have an appreciable antioxidant activity and might be useful as therapeutic agents. The remarkable antioxidant activities exhibited by stem bark and root methanol extracts have made them potential free radicals scavenging agents, and this is probably due to their phenolic, alkaloids, flavonoids, terpenoids and vitamins constituents (Sri-sudewi et al., 2014). These might be associated with the folkloric use of the plant in traditional medicine in Nigeria for the treatment of numerous diseases and health conditions such as malaria, fever, pains, diabetes and convulsion (Akuodor et al., 2015). The best antioxidant activities exhibited by stem bark methanol extract is probably due to the presence of hydroxyl group attached to the aromatic ring of their molecules. This is supported by the report of Akinmoladun et al., (2007) and Ahmad, (2011) where they stated that the mechanism of reduction of DPPH molecule by plant extracts or isolated pure

The antioxidant activity of the plant (stem and root) determined (Table 7) were expressed in terms of IC$_{50}$ value. *Vitellaria paradoxa* was found to possess lower DPPH scavenging activity compared to the standard drug. However, the scavenging ability of the stem bark extracts are higher than that of the root extracts. Moreover, smaller IC$_{50}$ values means better scavenging activity/antioxidant potential and higher IC$_{50}$ value, indicate lower activity (Cesur et al., 2017). This indicate that the *Vitellaria paradoxa* extracts have an appreciable antioxidant activity and might be useful as therapeutic agents. The remarkable antioxidant activities exhibited by stem bark and root methanol extracts have made them potential free radicals scavenging agents, and this is probably due to their phenolic, alkaloids, flavonoids, terpenoids and vitamins constituents (Sri-sudewi et al., 2014). These might be associated with the folkloric use of the plant in traditional medicine in Nigeria for the treatment of numerous diseases and health conditions such as malaria, fever, pains, diabetes and convulsion (Akuodor et al., 2015). The best antioxidant activities exhibited by stem bark methanol extract is probably due to the presence of hydroxyl group attached to the aromatic ring of their molecules. This is supported by the report of Akinmoladun et al., (2007) and Ahmad, (2011) where they stated that the mechanism of reduction of DPPH molecule by plant extracts or isolated pure
compounds or fractions is due to the presence of hydroxyl groups on their molecules. This mechanism is possible in plants that are rich in flavonoids, tannins, anthocyanins, and anthocyanidins because they met the structural requirements.

Acute toxicity studies of Vitellaria paradoxa stem bark and root were performed using the Lorke (1983) methods and using the limit dose test of Up and Down method. With careful observations of experimental animals from the first 30 minutes up to the 14th day, it was revealed that there were no deaths and any sign of toxicity such as loss or increase in weight, tiredness, abdominal constrict convulsion, hyperactive, weakness, diarrhea or increased diuresis within the short and long term effect in rats dosed with 5000 mg/kg body weight of the Vitellaria paradoxa extracts (stem and root methanol extracts). The outcome of the study of Alhassan et al. (2014) gave an LD₅₀ of 2000 mg/kg and this guided our choice of dose used (5000 mg/kg). The LD₅₀ was found to be greater than 5000 mg/kg body weight orally, and this suggested that the extract has low acute toxicity when administered orally. This may be attributed to the incomplete absorption brought about by inherent factors limiting absorption in the gastro intestinal tract (Dennis, 1984). The present study agrees with the work done by Prasanth et al., (2015); Ugbogu et al., (2016); Kofi et al., (2014) and Adesegun et al., (2016); . Bruce, (2006) reported that any substance with LD₅₀ estimated to be greater than 2000-5000 mg/kg body weight given orally could be considered to be of low toxicity and safe. Similarly, the chemical labelling and classification of acute systemic toxicity based on oral LD₅₀ values recommended by the Organization of Economic Cooperation and Development (OECD, Paris, France) and (Walum, 1998) are as follows: less than 5 mg/kg: very toxic, greater than 5 but less than 50 mg/kg: toxic, greater than 50 but less than 500 mg/kg: harmful, and, greater than 500 but less than 2000 mg/kg: no label. The very high LD₅₀ observed is not a conclusive finding about the safety of the extracts of Vitellaria paradoxa, higher doses could be tested for better understanding of its effects if use for a long period of time and for proper recommendation on its future utilization (Ogbonnia et al., 2011).

CONCLUSION

The established pharmacognostic standards for the powder of Vitellaria paradoxa stem bark and root could be used as a diagnostic tool for the standardization and identification of this medicinal plant for its purity and quality in the future and hence, inclusion into the pharmacopoeia for official use. The extracts have some secondary metabolites namely alkaloids, tannins, steroids, triterpenes, flavonoids, cardiac glycosides and saponins. The Acute toxicity (LD₅₀) of the stem bark and root extracts of Vitellaria paradoxa (Methanol) was found to be greater than 5000 mg /kg and is considered safe for use. The extracts have free radicals scavenging effects that are dose dependent. This supports the basis for the use of this plant traditionally for different ailments. The effects are probably due to phenolic compounds, flavonoids, tannins and some elements in the plant.
