Abstract

The problem of wave propagation in an infinite, homogeneous, transversely isotropic thermoelastic polygonal cross-sectional bar immersed in fluid is studied using Fourier expansion collocation method, with in the framework of linearized, three dimensional theory of thermoelasticity. Three displacement potential functions are introduced, to uncouple the equations of motion and the heat conduction. The frequency equations are obtained for longitudinal and flexural (symmetric and antisymmetric) modes of vibration and are studied numerically for triangular, square, pentagonal and hexagonal cross-sectional zinc bar. The computed non-dimensional wave numbers are presented in the form of dispersion curves.

Keywords: vibration of cylinder, thermal cylinder immersed in fluid, fluid loaded cylinder, solid-fluid interaction, transversely isotropic cylinder, rod immersed in fluid.

1. Introduction

The phenomenon of thermoelastic bar of polygonal cross sections immersed in a fluid finds a wide range of applications in all fields of science and engineering including atomic physics and metallurgy. Nagaya (1981, 1982, 1983, 1985) discussed wave propagation in an infinite bar of arbitrary cross section and the wave propagation in an infinite cylinder of both inner and outer arbitrary cross section applicable to a bar of general cross section, based on three-dimensional theory of elasticity. The boundary conditions along the free surface of arbitrary cross section are satisfied by means of Fourier expansion collocation method. Sinha et al. (1992) have studied the axisymmetric wave propagation in circular cylindrical shell immersed in a fluid, in two parts. In Part I, the theoretical analysis of the propagation modes is discussed and in Part II, the axisymmetric modes excluding tensional modes are obtained theoretically and experimentally and are compared. Berliner and Soiecki (1996) have studied the wave propagation in a fluid loaded transversely isotropic cylinder. In that paper, Part I consists of the analytical formulation of the frequency equation of the coupled system consisting of the cylinder with inner and outer fluid and Part II gives the numerical results. Easwaran and Munjal (1995) investigated the effect of wall compliance on lowest order mode propagation in a fluid filled or submerged impedance tubes. Based on the closed form analytical solution of the coupled wave equations and applying the boundary conditions at the fluid-solid interface, an eigenquation was obtained and then the dispersion behavior of wave motion was analyzed. Also, they investigated axial attenuation characteristics of plane waves along water filled tubes submerged in water or air.

Suhubi (1964) studied the longitudinal vibration of a circular cylinder coupled with a thermal field. Later with Erbay (Erbay and Suhubi, 1986) he studied the longitudinal wave propagation in a generalized thermoelastic infinite cylinder and obtained the dispersion relation for a constant surface temperature of the cylinder. Lord and Shulman (1967) formulated a generalized dynamical theory of thermoelasticity using the heat transport equation that included the time needed for the acceleration of heat flow. Green and Lindsay (1972) presented an alternative generalization of classical thermoelasticity. Restrictions on constitutive
equations were discussed with the help of an entropy production inequality proposed by Green and Laws. They have showed that the linear heat conduction tensor was symmetric and that the theory allows for second sound effects. Venkatesan and Ponnusamy (2002, 2007) studied the wave propagation in solid and generalized solid cylinder of arbitrary cross-sections immersed in fluid using the Fourier expansion collocation method. Dayal (1993) investigated the free vibrations of a fluid loaded transversely isotropic rod based on uncoupling the radial and axial wave equations by introducing scalar and vector potentials. Nagy (1995) studied the propagation of longitudinal guided waves in fluid-loaded transversely isotropic rod based on the superposition of partial waves. Guided waves in a transversely isotropic cylinder immersed in a fluid was analyzed by Ahmad (2001). Ponnusamy (2007) and later with Rajagopal (Ponnusamy and Rajagopal, 2010) have studied, the wave propagation in a generalized thermoelastic solid cylinder of arbitrary cross-section and in a homogeneous transversely isotropic thermo elastic solid cylinder of arbitrary cross-sections respectively using the Fourier expansion collocation method.

In this paper, the wave propagation in a transversely isotropic thermoelastic solid bar of polygonal cross-section immersed in fluid is studied using Fourier expansion collocation method. The frequency equations are obtained for longitudinal and flexural (symmetric and antisymmetric) modes of vibration and are studied numerically for triangular, square, pentagonal and hexagonal cross-sectional Zinc bars. The computed non-dimensional wave numbers are presented in the form of dispersion curves.

2. Formulation of the problem

In this section, we consider a homogeneous transversely isotropic, thermally conducting elastic bar of infinite length immersed in fluid with uniform temperature $T_0$ in the undisturbed state initially. $u_r$, $u_\theta$ and $u_z$ are respectively the radial, tangential and axial displacement components, which are defined through the cylindrical coordinates $r$, $\theta$ and $z$.

The governing field equations of motion and heat conduction in the absence of body force are Sharma and Sharma (2002):

\[ \sigma_{rr,r} + r^{-1} \sigma_{r\theta,\theta} + \sigma_{rz,z} + r^{-1} (\sigma_{r\theta} - \sigma_{\theta\theta}) = \rho u_{r,tt} \]
\[ \sigma_{r\theta,r} + r^{-1} \sigma_{\theta\theta,\theta} + \sigma_{z\theta,z} + 2r^{-1} \sigma_{r\theta} = \rho u_{\theta,tt} \]
\[ \sigma_{rz,r} + r^{-1} \sigma_{z\theta,\theta} + \sigma_{zz,z} + r^{-1} \sigma_{rz} = \rho u_{z,tt} \]
\[ K_1 (T_{rr,r} + r^{-2} T_{r\theta,\theta}) + K_3 T_{zz,z} - \rho c_v T = T_0 \left( \beta_1 (e_{rr} + e_{\theta\theta}) + \beta_3 e_{zz} \right) \]

and

\[ \sigma_{rr} = c_{11} e_{rr} + c_{12} e_{\theta\theta} + c_{13} e_{zz} - \beta_1 T \]
\[ \sigma_{\theta\theta} = c_{12} e_{rr} + c_{11} e_{\theta\theta} + c_{13} e_{zz} - \beta_1 T \]
\[ \sigma_{zz} = c_{13} e_{rr} + c_{13} e_{\theta\theta} + c_{33} e_{zz} - \beta_3 T \]
\[ \sigma_{r\theta} = c_{66} e_{r\theta}, \sigma_{z\theta} = c_{44} e_{z\theta}, \sigma_{rz} = c_{44} e_{rz} \]

where $\sigma_{rr}$, $\sigma_{\theta\theta}$, $\sigma_{zz}$, $\sigma_{r\theta}$, $\sigma_{z\theta}$, $\sigma_{rz}$ are the stress components, $e_{rr}$, $e_{\theta\theta}$, $e_{zz}$, $e_{r\theta}$, $e_{z\theta}$, $e_{rz}$ are the strain components, $T$ is the temperature change about the equilibrium temperature $T_0$, $c_{11}$, $c_{12}$, $c_{13}$, $c_{33}$, $c_{44}$ and $c_{66} = (c_{11} - c_{12})/2$ are the five elastic constants, $\beta_1$, $\beta_3$ and $K_1$, $K_3$ respectively thermal expansion coefficients and thermal conductivities along and perpendicular to the symmetry, $\rho$ is the mass density, $c_v$ is the specific heat capacity.

The strain $e_{ij}$ are related to the displacements are given by

\[ e_{rr} = u_{r,r}, e_{\theta\theta} = r^{-1} \left( u_r + u_{\theta,\theta} \right), e_{zz} = u_{z,z} \]
\[ e_{r\theta} = \left( u_{\theta,r} + r^{-1} (u_r - u_{\theta,\theta}) \right), e_{r\theta} = \left( u_{\theta,z} + r^{-1} u_{z,r} \right), e_{rz} = u_{z,r} + u_{r,z} \]

The comma in the subscripts denotes the partial differentiation with respect to the variables.

Substituting the Eqs. (3) and (2) in the Eq. (1), results in the following three-dimensional equations of motion and heat conduction are obtained as follows:

\[ c_{11} \left( u_{r,rr} + r^{-1} u_{r,r} - r^{-2} u_r \right) - r^{-2} (c_{11} + c_{66}) u_{\theta,\theta} + r^{-2} c_{44} u_{r,\theta\theta} \]
\[ + c_{44} u_{r,zz} + (c_{44} + c_{13}) u_{z,rr} + r^{-1} (c_{66} + c_{12}) u_{\theta,r\theta} - \beta_1 T = \rho u_{r,tt} \]
3. Solutions of the Field Equation

To obtain propagation of harmonic waves in polygonal cross-sectional bars, we assume solutions of the displacement components to be expressed in terms of derivatives of potentials first introduced by Mirsky (1964) and used as well by Berliner and Solecki (1996). Thus, we seek the solution of the Eq. (4) in the form Mirsky (1964) as

\[
\begin{align*}
\phi_n(r, \theta, z, t) &= \sum_{n=0}^{\infty} \epsilon_n \left[ (\phi_{n,r} + r^{-1} \psi_{n,\theta}) + (\tilde{\phi}_{n,r} + r^{-1} \tilde{\psi}_{n,\theta}) \right] e^{i(kz+\omega t)} \\
\psi_n(r, \theta, z, t) &= \sum_{n=0}^{\infty} \epsilon_n \left[ (r^{-1} \phi_{n,\theta} - \psi_{n,r}) + (r^{-1} \tilde{\phi}_{n,\theta} - \tilde{\psi}_{n,r}) \right] e^{i(kz+\omega t)} \\
W_n(r, \theta, z, t) &= (i/a) \sum_{n=0}^{\infty} \epsilon_n \left[ W_n + \tilde{W}_n \right] e^{i(kz+\omega t)} \\
T_n(r, \theta, z, t) &= \left( \frac{c_{44}}{\beta} \right) a^2 \sum_{n=0}^{\infty} \epsilon_n \left[ T_n + \tilde{T}_n \right] e^{i(kz+\omega t)}
\end{align*}
\]

where \( \epsilon_n = 1/2 \) for \( n = 0 \), \( \epsilon_n = 1 \) for \( n \geq 1 \), \( i = \sqrt{-1} \), \( k \) is the wave number, \( \omega \) is the frequency, \( \phi_n(r, \theta) \), \( W_n(r, \theta) \) and \( \psi_n(r, \theta) \) are the displacement potentials and \( T_n(r, \theta) \) is the temperature change for the symmetric mode and the barred quantities are the displacement potentials and temperature change for the antisymmetric modes of vibration and \( a \) is the geometrical parameter of the bar.

By introducing the dimensionless quantities such as \( x = r/a \), \( \zeta = k/a \), \( \Omega^2 = \rho \omega^2 a^2 / c_{44} \), \( c_{11} = c_{11} / c_{44} \), \( c_{13} = c_{13} / c_{44} \), \( \rho = \rho / c_{44} \), \( \beta = \beta / \beta_3 \), \( k = \left( \rho c_{44} \right)^{1/2} / \beta_3 T_0 a \Omega \), \( d = \rho c_{44} / \beta_3^2 T_0 \) and substituting Eq. (5) in Eq. (4), we obtain

\[
\begin{align*}
\bar{c}_{11} \nabla^2 \phi_n - \zeta (1 + c_{13}) W_n - \bar{\beta} T_n &= 0 \\
\zeta (1 + c_{13}) \nabla^2 \psi_n + \left( \Omega^2 - c_{33} \zeta^2 \right) W_n - \zeta T_n &= 0 \\
\bar{\beta} \nabla^2 \phi_n - \zeta W_n + (d + i k_3 \zeta \zeta^2) T_n &= 0
\end{align*}
\]

and

\[
\left( \nabla^2 + \left( \Omega^2 - \zeta^2 \right) / c_{66} \right) \psi_n = 0
\]

where \( \nabla^2 \equiv \partial^2 / \partial x^2 + x^{-1} \partial / \partial x + x^{-2} \partial^2 / \partial \theta^2 \)

The Eq. (6) can be written as

\[
\begin{align*}
-\bar{c}_{11} \nabla^2 \phi_n - \zeta (1 + c_{13}) W_n - \bar{\beta} T_n &= 0 \\
\zeta (1 + c_{13}) \nabla^2 \psi_n + \left( \Omega^2 - c_{33} \zeta^2 \right) W_n - \zeta T_n &= 0 \\
\bar{\beta} \nabla^2 \phi_n - \zeta W_n + (d + i k_3 \zeta \zeta^2) T_n &= 0
\end{align*}
\]
Equation (8), on simplification reduces to the following differential equation:

\[
\left( A\nabla^6 + B\nabla^4 + C\nabla^2 + D \right) (\phi_n, W_n, T_n) = 0
\]  

(9)

where

\[
A = ic_{11}k_1
\]

\[
B = ik_1\left( (\Omega^2 - c_{33}\zeta^2)c_{11} + (\Omega^2 - \zeta^2) + \zeta^2(1 + c_{13})^2 \right) + c_{11}\left( d - ik_3\zeta^2 \right) + \beta^2
\]

\[
C = c_{11}\left( \Omega^2 - c_{33}\zeta^2 \right) \left[ (d - \zeta(1 + ik_3)) + (\Omega^2 - \zeta^2) \left( (d - ik_3\zeta^2) + ik_1(\Omega^2 - c_{33}\zeta^2) \right) \right]
\]

\[
+ (1 + c_{13})^2 \left[ \zeta^2(1 + ic_{33}\zeta^2) + \beta \zeta^2 \right] + \beta \zeta^2(1 + c_{13})
\]

\[
D = (\Omega^2 - \zeta^2) \left[ (\Omega^2 - c_{33}\zeta^2)(d - ik_3\zeta^2) - \zeta^2 \right]
\]

(10d)

Factorizing the relation given in Eq. (9) into cubic equation for \((\alpha, a)^2, (i = 1, 2, 3)\), the solutions for the symmetric modes are obtained as

\[
\phi_n = \sum_{i=1}^{3} A_{ia} J_n (\alpha, a) \cos nt
\]

(11a)

\[
W_n = \sum_{i=1}^{3} d_{ia} A_{ia} J_n (\alpha, a) \cos nt
\]

(11b)

\[
T_n = \sum_{i=1}^{3} e_{ia} A_{ia} J_n (\alpha, a) \cos nt
\]

(11c)

The solutions for the antisymmetric modes \(\phi_n, W_n\) and \(T_n\) are obtained by replacing \(\cos nt\) by \(\sin nt\) in Eq. (11). Since we are considering a solid bar of polygonal cross-section, the Bessel function of the second kind \(Y_n\) is absent. Here \((\alpha, a)^2 > 0\), \((i = 1, 2, 3)\) are the roots of the algebraic equation

\[
A(\alpha a)^6 - B(\alpha a)^4 + C(\alpha a)^2 + D = 0
\]

(12)

The solutions corresponding to the root \((\alpha, a)^2 = 0\) is not considered here, since \(J_n(0)\) is zero, except for \(n = 0\). The Bessel function \(J_n\) is used when the roots \((\alpha, a)^2, (i = 1, 2, 3)\) are real or complex and the modified Bessel function \(I_n\) is used when the roots \((\alpha, a)^2, (i = 1, 2, 3)\) are imaginary.

The constants \(d_i\) and \(e_i\) defined in the Eq. (11) can be calculated from the equations

\[
\zeta(1 + c_{13})d_i + \beta e_i = -\left( c_{11}(\alpha, a)^2 - \Omega^2 + \zeta^2 \right)
\]

(13a)
\[
\left((\Omega^2 - \zeta_3^2) - (\alpha_4 a)^2\right) d_i - \zeta e_i = (\alpha_4 a)^2 \left(1 + \zeta_1 b\right) \zeta
\]  
(13b)

Solving the Eq. (7), the solution to the symmetric mode is obtained as
\[
\psi_n = A_{an} J_n (\alpha_4 ax) \sin n\theta
\]  
(14)
where \((\alpha_4 a)^2 = \Omega^2 - \zeta^2\). If \((\alpha_4 a)^2 < 0\), the Bessel function \(J_n\) is replaced by the modified Bessel function \(I_n\). The solution for the antisymmetric mode \(\tilde{\psi}_n\) is obtained from Eq. (14) by replacing \(\sin n\theta\) by \(\cos n\theta\).

4. Equations of motion of the fluid

In cylindrical polar coordinates \(r, \theta\) and \(z\) the acoustic pressure and radial displacement equation of motion for an invicid fluid are of the form (Achenbach, 1973):
\[
p^f = -B^f \left(u^f_r + r^{-1}(u^f_\theta + u^f_\phi)\right) + u^f_z
\]  
(15)
and
\[
c\,^2 u^f_{rt} = \Delta_r
\]  
(16)
respectively. Where \(B^f\) is the adiabatic bulk modulus, \(\rho^f\) is the density, \(c^f = \sqrt{B^f / \rho^f}\) is the acoustic phase velocity in the fluid, and
\[
\Delta = \left(u^f_r + r^{-1}(u^f_\theta + u^f_\phi)\right) + u^f_z.
\]  
(17)
Substituting
\[
u^f_r = \phi^f_r, \quad u^f_\theta = r^{-1}\phi^f_\theta \quad \text{and} \quad u^f_z = \phi^f_z
\]  
(18)
and seeking the solution of (16) in the form
\[
\phi^n (r, \theta, z, t) = \sum_{n=0}^{\infty} e_{\phi n} \phi^n_n (r) \cos n\theta e^{i(kz + ax)}.
\]  
(19)
The fluid that represents the oscillatory waves propagating away is given as
\[
\phi^n_n = A_{an} H_n^{(1)}(\alpha_n ax)
\]  
(20)
where \((\alpha_n a)^2 = \Omega^2 / \rho^f B^f = \zeta^2\), in which \(\rho = \rho^f, B = B^f / c^4, H_n^{(1)}\) is the Hankel function of the first kind.

If \((\alpha_n a)^2 < 0\), then the Hankel function of first kind is to be replaced by \(K_n\), where \(K_n\) is the modified Bessel function of the second kind. By substituting Eq.(19) in Eq. (15) along with Eq.(20), the acoustic pressure for the fluid can be expressed as
\[
p^f = \sum_{n=0}^{\infty} e_{\phi n} A_{an} \Omega^2 \rho H_n^{(1)}(\alpha_n ax) \cos n\theta e^{i(kz + ax)}
\]  
(21)

5. Boundary conditions and Frequency equations

In this problem, the free vibration of a transversely isotropic thermoelastic solid bar of polygonal cross-section is considered. Since the boundary is irregular, the Fourier expansion collocation method is applied on the boundary of the cross-section. Thus, the boundary conditions obtained are
\[
\left(\sigma_{pp} + p^f\right)_i = \left(\sigma_{pq}\right)_i = \left(\sigma_{qp}\right)_i = \left(u_r - u_r^f\right)_i = (T)_i = 0.
\]  
(22)
where \(p\) is the coordinate normal to the boundary and \(q\) is the coordinate in the tangential direction. Here \(\sigma_{pp}\) is the normal stress, \(\sigma_{pq}\) and \(\sigma_{qp}\) are the shearing stresses and \(\left(\_\right)_i\) is the value at the \(i\)-th segment of the boundary. Since the coordinate \(p\) and \(q\) are functions of \(r\) and \(\theta\), it is difficult to find transformed expressions for the stresses. Therefore the polygonal boundary is divided into small segments such that the variations of the stresses are assumed to be constant. Assuming the angle \(\gamma_i\), between the normal to the segment and the reference axis to be constant, the transformed expressions for the stresses are followed by Nagaya (1983).
\[ \sigma_{pp} = \left( c_{11} \cos^2(\theta - \gamma_i) + c_{12} \sin^2(\theta - \gamma_i) \right) u_{r,r} + r^{-1} \left( c_{11} \sin^2(\theta - \gamma_i) + c_{12} \cos^2(\theta - \gamma_i) \right) \left( u_r + u_{\theta,\theta} \right) \\
+ c_{66} \left( r^{-1} \left( u_{\theta} - u_{r,\theta} \right) - u_{\theta,\theta} \right) \sin 2(\theta - \gamma_i) + c_{13} u_{z,z} - \beta T \]  
(23a)

\[ \sigma_{pq} = c_{66} \left( r^{-1} \left( u_{\theta} - u_{r,\theta} \right) + u_{\theta,\theta} \right) \sin 2(\theta - \gamma_i) + \left( r^{-1} \left( u_{\theta} - u_{r,\theta} \right) + u_{\theta,\theta} \right) \cos 2(\theta - \gamma_i) \]  
(23b)

\[ \sigma_{zp} = c_{44} \left( u_{r,z} + u_{z,r} \right) \cos(\theta - \gamma_i) - \left( u_{\theta,z} + r^{-1} u_{r,\theta} \right) \sin(\theta - \gamma_i) \]  
(23c)

Applying the Fourier expansion collocation method along the curved surface of the boundary, the transformed expressions for the stresses are

\[ \left[ \left( S_{pp} \right)_i + \left( \overline{S}_{pp} \right)_i \right] e^{i(\tilde{z} + \Omega t)} = 0 \]  
(24a)

\[ \left[ \left( S_{pq} \right)_i + \left( \overline{S}_{pq} \right)_i \right] e^{i(\tilde{z} + \Omega t)} = 0 \]  
(24b)

\[ \left[ \left( S_{zp} \right)_i + \left( \overline{S}_{zp} \right)_i \right] e^{i(\tilde{z} + \Omega t)} = 0 \]  
(24c)

\[ \left[ \left( S_{z} \right)_i + \left( \overline{S}_{z} \right)_i \right] e^{i(\tilde{z} + \Omega t)} = 0 \]  
(24d)

\[ \left[ \left( S_{z} \right)_i + \left( \overline{S}_{z} \right)_i \right] e^{i(\tilde{z} + \Omega t)} = 0 \]  
(24d)

where,

\[ S_{pp} = 0.5 \left( A_{10} e_0^1 + A_{20} e_0^2 + A_{30} e_0^3 + A_{30} e_0^5 \right) + \sum_{n=1}^{\infty} \left( A_{1n} e_n^1 + A_{2n} e_n^2 + A_{3n} e_n^3 + A_{4n} e_n^4 + A_{5n} e_n^5 \right) \]  
(25a)

\[ S_{pq} = 0.5 \left( A_{10} f_0^1 + A_{20} f_0^2 + A_{30} f_0^3 \right) + \sum_{n=1}^{\infty} \left( A_{1n} f_n^1 + A_{2n} f_n^2 + A_{3n} f_n^3 + A_{4n} f_n^4 \right) \]  
(25b)

\[ S_{zp} = 0.5 \left( A_{10} g_0^1 + A_{20} g_0^2 + A_{30} g_0^3 \right) + \sum_{n=1}^{\infty} \left( A_{1n} g_n^1 + A_{2n} g_n^2 + A_{3n} g_n^3 + A_{4n} g_n^4 \right) \]  
(25c)

\[ S_{z} = 0.5 \left( A_{10} h_0^1 + A_{20} h_0^2 + A_{30} h_0^3 + A_{40} h_0^5 \right) + \sum_{n=1}^{\infty} \left( A_{1n} h_n^1 + A_{2n} h_n^2 + A_{3n} h_n^3 + A_{4n} h_n^4 + A_{5n} h_n^5 \right) \]  
(25d)

\[ \overline{S}_{pp} = 0.5 \overline{A}_{40} \overline{e}_0^4 + \sum_{n=1}^{\infty} \left( \overline{A}_{1n} \overline{e}_n^1 + \overline{A}_{2n} \overline{e}_n^2 + \overline{A}_{3n} \overline{e}_n^3 + \overline{A}_{4n} \overline{e}_n^4 + \overline{A}_{5n} \overline{e}_n^5 \right) \]  
(26a)

\[ \overline{S}_{pq} = 0.5 \overline{A}_{40} \overline{f}_0^4 + \sum_{n=1}^{\infty} \left( \overline{A}_{1n} \overline{f}_n^1 + \overline{A}_{2n} \overline{f}_n^2 + \overline{A}_{3n} \overline{f}_n^3 + \overline{A}_{4n} \overline{f}_n^4 \right) \]  
(26b)

\[ \overline{S}_{zp} = 0.5 \overline{A}_{40} \overline{g}_0^4 + \sum_{n=1}^{\infty} \left( \overline{A}_{1n} \overline{g}_n^1 + \overline{A}_{2n} \overline{g}_n^2 + \overline{A}_{3n} \overline{g}_n^3 + \overline{A}_{4n} \overline{g}_n^4 \right) \]  
(26c)

\[ \overline{S}_{z} = 0.5 \overline{A}_{40} \overline{h}_0^4 + \sum_{n=1}^{\infty} \left( \overline{A}_{1n} \overline{h}_n^1 + \overline{A}_{2n} \overline{h}_n^2 + \overline{A}_{3n} \overline{h}_n^3 + \overline{A}_{4n} \overline{h}_n^4 + \overline{A}_{5n} \overline{h}_n^5 \right) \]  
(26d)

\[ \overline{S}_{z} = \sum_{n=1}^{\infty} \left( \overline{A}_{1n} \overline{k}_n^1 + \overline{A}_{2n} \overline{k}_n^2 + \overline{A}_{3n} \overline{k}_n^3 \right) \]  
(26e)

The functions \( e^i - \overline{e}^i_n \) used in the boundary conditions of the symmetric and antisymmetric cases are given in Appendix A. The boundary conditions along the entire range of the boundary cannot be satisfied directly. To satisfy the boundary conditions, the Fourier expansion collocation method due to Nagaya (1983) is applied along the boundary. Performing the Fourier series expansion to the transformed expression in Eq. (22) along the boundary, the boundary conditions are expanded in the form of
double Fourier series for symmetric and antisymmetric modes of vibrations. For the symmetric mode, the equation, which satisfies the boundary conditions, is obtained in matrix form as follows:

\[
\begin{bmatrix}
E_{00}^1 & E_{00}^3 & E_{00}^5 & E_{01}^1 & \cdots & E_{0N}^1 & E_{01}^3 & \cdots & E_{0N}^3 & E_{01}^5 & \cdots & E_{0N}^5 & E_{10}^1 & \cdots & A_{10} \\
\vdots & \vdots & \vdots & \vdots & \cdots & \vdots & \vdots & \cdots & \vdots & \vdots & \cdots & \vdots & \vdots & A_{20} \\
E_{10}^1 & E_{10}^3 & E_{10}^5 & E_{11}^1 & \cdots & E_{1N}^1 & E_{11}^3 & \cdots & E_{1N}^3 & E_{11}^5 & \cdots & E_{1N}^5 & E_{20}^1 & \cdots & A_{20} \\
F_{10}^1 & F_{10}^3 & F_{10}^5 & F_{11}^1 & \cdots & F_{1N}^1 & F_{11}^3 & \cdots & F_{1N}^3 & F_{11}^5 & \cdots & F_{1N}^5 & F_{20}^1 & \cdots & A_{20} \\
\vdots & \vdots & \vdots & \vdots & \cdots & \vdots & \vdots & \cdots & \vdots & \vdots & \cdots & \vdots & \vdots & A_{30} \\

\end{bmatrix} \begin{bmatrix}
\epsilon_1 \\
\epsilon_2 \\
\epsilon_3 \\
\epsilon_4 \\
\epsilon_5 \\
\end{bmatrix} = 0
\]

(27)

where,

\[
E_{mn}^j = (2\varepsilon_n / \pi) \sum_{l=1}^{I} \int_{\theta_{l-1}}^{\theta_l} e_n^r (R, \theta) \cos m \theta d\theta
\]

\[
F_{mn}^j = (2\varepsilon_n / \pi) \sum_{l=1}^{I} \int_{\theta_{l-1}}^{\theta_l} f_n^r (R, \theta) \sin m \theta d\theta
\]

\[
G_{mn}^j = (2\varepsilon_n / \pi) \sum_{l=1}^{I} \int_{\theta_{l-1}}^{\theta_l} g_n^r (R, \theta) \cos m \theta d\theta
\]

\[
H_{mn}^j = (2\varepsilon_n / \pi) \sum_{l=1}^{I} \int_{\theta_{l-1}}^{\theta_l} h_n^r (R, \theta) \cos m \theta d\theta
\]

\[
K_{mn}^j = (2\varepsilon_n / \pi) \sum_{l=1}^{I} \int_{\theta_{l-1}}^{\theta_l} k_n^r (R, \theta) \cos m \theta d\theta
\]

(28)

Here \( i = 1, 2, 3, 4 \) and \( 5, I \) is the number of segments, \( R \) is the coordinate at the boundary and \( N \) is the number of terms in the Fourier series.

The boundary conditions for the antisymmetric modes are written in the form of a matrix as given below:
The Fourier coefficients \( \tilde{E}_{mn}, \tilde{F}_{mn}, \tilde{G}_{mn}, \tilde{H}_{mn}, \tilde{K}_{mn} \) are obtained by replacing \( \cos m\theta \) by \( \sin m\theta \) and \( \sin m\theta \) by \( \cos m\theta \) in Eq. (28). For the nontrivial solutions of the systems of equations, given in Eqs. (27) and (29), the determinant of the coefficient matrix must vanish and these determinants give the frequencies of symmetric and antisymmetric modes of vibration respectively.

6. Particular case

For isotropic materials, \( c_{11} = c_{33} = \lambda + 2\mu , \quad c_{44} = \mu , \quad c_{13} = \lambda , \quad c_{12} = c_{13} \) and \( c_{66} = c_{66} = \left( c_{11} - c_{12} \right) / 2 \) (30)

Where \( \lambda \) and \( \mu \) are Lame’s constant.

Using the values in various relevant relations and equations, along with \( \beta_1 = \beta_2 = 0 \) and \( K_1 = K_3 = 0 \), the problem is reduced to free vibration analysis of polygonal cross sectional bar immersed in fluid. Also, the frequency equations obtained in this method matches well with the frequency equations of Venkatesan and Ponnusamy (2007) which shows the exactness of our method.

A. 6.1 Frequency equation of polygonal cross-sectional plate

Substituting the wave number \( k = 0 \) in the corresponding expressions and solutions in the previous sections, the problem is converted to two-dimensional vibration analysis of polygonal cross-sectional plate immersed in fluid. The boundary conditions for a polygonal cross-sectional plate immersed in fluid is obtained as follows

\[
\left( \sigma_{pp}^i + p_f^i \right)_i = \left( \sigma_{pq}^i \right)_i = \left( u - u_f^i \right)_i = 0
\]

(31)

the stresses \( \sigma_{pp}^i \) and \( \sigma_{pq}^i \), \( u \) and \( u_f^i \) have the same meaning as discussed in the previous sections.

Performing the Fourier series expansion as discussed in the previous sections to Eq. (31) along the boundary, the boundary conditions along the surfaces are expanded in the form of double Fourier series. For the symmetric mode, the boundary conditions are expressed as follows.

\[
\sum_{m=0}^{\infty} c_n \left[ X_{n0} A_{10} + X_{n0}^2 A_{20} + \sum_{n=1}^{\infty} \left( X_{mn} A_{1n} + X_{mn}^2 A_{2n} + X_{mn}^3 A_{3n} \right) \right] \cos m\theta = 0
\]

\[
\sum_{m=1}^{\infty} \left[ Y_{n0} A_{10} + Y_{n0}^2 A_{20} + \sum_{n=1}^{\infty} \left( Y_{mn} A_{1n} + Y_{mn}^2 A_{2n} + Y_{mn}^3 A_{3n} \right) \right] \sin m\theta = 0
\]
\[
\sum_{m=0}^{\infty} e_m \left[ Z_{m0} A_{00} + Z_{m0}^2 A_{20} + \sum_{n=1}^{\infty} \left( Z_{mn}^1 A_{1n} + Z_{mn}^2 A_{2n} + Z_{mn}^3 A_{3n} \right) \right] \cos m\theta = 0
\] (32)

Similarly, for antisymmetric mode, the boundary conditions are expressed as

\[
\sum_{m=0}^{\infty} e_m \left[ \bar{X}_{m0} A_{10} + \sum_{n=1}^{\infty} \left( \bar{X}_{mn} A_{1n} + \bar{X}_{mn}^2 A_{2n} + \bar{X}_{mn}^3 A_{3n} \right) \right] \sin m\theta = 0
\]

\[
\sum_{m=0}^{\infty} e_m \left[ \bar{Y}_{m0} A_{10} + \sum_{n=1}^{\infty} \left( \bar{Y}_{mn} A_{1n} + \bar{Y}_{mn}^2 A_{2n} + \bar{Y}_{mn}^3 A_{3n} \right) \right] \cos m\theta = 0
\]

\[
\sum_{m=0}^{\infty} e_m \left[ \bar{Z}_{m0} A_{10} + \sum_{n=1}^{\infty} \left( \bar{Z}_{mn} A_{1n} + \bar{Z}_{mn}^2 A_{2n} + \bar{Z}_{mn}^3 A_{3n} \right) \right] \sin m\theta = 0
\] (33)

Where

\[ X_j^m = (2e_j / \pi) \sum_{l=1}^{\infty} f_{j}^l (R_{j}, \theta) \cos m\theta d\theta , \quad Y_j^m = (2e_j / \pi) \sum_{l=1}^{\infty} g_{j}^l (R_{j}, \theta) \sin m\theta d\theta \]

\[ Z_j^m = (2e_j / \pi) \sum_{l=1}^{\infty} \tilde{f}_{j}^l (R_{j}, \theta) \cos m\theta d\theta , \quad \bar{X}_j^m = (2e_j / \pi) \sum_{l=1}^{\infty} \tilde{g}_{j}^l (R_{j}, \theta) \sin m\theta d\theta \]

\[ \bar{Y}_j^m = (2e_j / \pi) \sum_{l=1}^{\infty} \tilde{f}_{j}^l (R_{j}, \theta) \cos m\theta d\theta , \quad \bar{Z}_j^m = (2e_j / \pi) \sum_{l=1}^{\infty} \tilde{g}_{j}^l (R_{j}, \theta) \sin m\theta d\theta \] (34)

and where \( j = 1, 2, \) and \( 3 \), \( I \) is the number of segments, \( R_j \) is the coordinate \( r \) at the boundary and \( N \) is the number of truncation of the Fourier series. The frequency equations are obtained by truncating the series to \( N + 1 \) terms, and equating the determinant of the coefficients of the amplitude \( A_{in} = 0 \) and \( \bar{A}_{in} = 0 \), for symmetric and antisymmetric modes of vibrations. Thus, the frequency equation for the symmetric mode is obtained from Eq. (32), by equating the determinant of the coefficient matrix of \( A_{in} = 0 \). Therefore we have

\[
\begin{vmatrix}
X_{00}^1 & X_{00}^2 & X_{01}^1 & \ldots & X_{0N}^1 & X_{01}^2 & \ldots & X_{0N}^2 & \ldots & X_{01}^3 & \ldots & X_{0N}^3 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \ddots & \vdots & \ddots & \vdots \\
X_{N0}^1 & X_{N0}^2 & X_{N1}^1 & \ldots & X_{NN}^1 & X_{N1}^2 & \ldots & X_{NN}^2 & \ldots & X_{N1}^3 & \ldots & X_{NN}^3 \\
Y_{00}^1 & Y_{00}^2 & Y_{01}^1 & \ldots & Y_{0N}^1 & Y_{01}^2 & \ldots & Y_{0N}^2 & \ldots & Y_{01}^3 & \ldots & Y_{0N}^3 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \ddots & \vdots & \ddots & \vdots \\
Y_{N0}^1 & Y_{N0}^2 & Y_{N1}^1 & \ldots & Y_{NN}^1 & Y_{N1}^2 & \ldots & Y_{NN}^2 & \ldots & Y_{N1}^3 & \ldots & Y_{NN}^3 \\
Z_{00}^1 & Z_{00}^2 & Z_{01}^1 & \ldots & Z_{0N}^1 & Z_{01}^2 & \ldots & Z_{0N}^2 & \ldots & Z_{01}^3 & \ldots & Z_{0N}^3 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \ddots & \vdots & \ddots & \vdots \\
Z_{N0}^1 & Z_{N0}^2 & Z_{N1}^1 & \ldots & Z_{NN}^1 & Z_{N1}^2 & \ldots & Z_{NN}^2 & \ldots & Z_{N1}^3 & \ldots & Z_{NN}^3 \\
\end{vmatrix} = 0
\] (35)

Similarly, the frequency equation for antisymmetric mode is obtained from the eq. (33) by equating the determinant of the coefficient matrix of \( A_{in} = 0 \). Therefore, for the antisymmetric mode, the frequency equation obtained as
\[ \begin{align*}
\bar{X}_0^3 & \quad \bar{X}_1^3 \quad \cdots \quad \bar{X}_N^3 \\
\vdots & \quad \vdots \quad \cdots \quad \vdots \\
\bar{X}_{N}^3 & \quad \bar{X}_{N+1}^3 \quad \cdots \quad \bar{X}_{2N}^3 \\
\vdots & \quad \vdots \quad \cdots \quad \vdots \\
\bar{Y}_0^3 & \quad \bar{Y}_1^3 \quad \cdots \quad \bar{Y}_N^3 \\
\vdots & \quad \vdots \quad \cdots \quad \vdots \\
\bar{Y}_{N}^3 & \quad \bar{Y}_{N+1}^3 \quad \cdots \quad \bar{Y}_{2N}^3 \\
\vdots & \quad \vdots \quad \cdots \quad \vdots \\
\bar{Z}_0^3 & \quad \bar{Z}_1^3 \quad \cdots \quad \bar{Z}_N^3 \\
\vdots & \quad \vdots \quad \cdots \quad \vdots \\
\bar{Z}_{N}^3 & \quad \bar{Z}_{N+1}^3 \quad \cdots \quad \bar{Z}_{2N}^3 \\
\vdots & \quad \vdots \quad \cdots \quad \vdots \\
\end{align*} \]

\[ = 0 \]  

(36)

where

\[ e_i^n = 2 \left\{ n(n-1)J_n(\alpha,ax) + (\alpha,ax)J_{n+1}(\alpha,ax) \right\} \cos 2(\theta - \gamma_i) \cos n\theta \]

\[ -x^2 \left\{ (\alpha,ax)^2 \left( \bar{Z}_i + 2 \cos^2 (\theta - \gamma_i) \right) \right\} J_n(\alpha,ax) \cos n\theta, i = 1, 2 \]

\[ e_i^n = \Omega^2 \rho \bar{H}^{(i)}(\alpha,ax) \cos n\theta \]

\[ f_i^n = 2 \left\{ n(n-1) - (\alpha,ax)^2 J_n(\alpha,ax) + (\alpha,ax)J_{n+1}(\alpha,ax) \right\} \sin 2(\theta - \gamma_i) \cos n\theta + 2n \left\{ (\alpha,ax)J_{n+1}(\alpha,ax) - (n-1)J_n(\alpha,ax) \right\} \cos 2(\theta - \gamma_i) \sin n\theta, i = 1, 2 \]

\[ f_i^n = 0 \]

\[ g_i^n = \left\{ nJ_n(\alpha,ax) - (\alpha,ax)J_{n+1}(\alpha,ax) \right\} \cos n\theta, i = 1, 2 \]

\[ g_i^n = -\left[ nH^{(i)}(\alpha,ax) - (\alpha,ax)H^{(i+1)}(\alpha,ax) \right] \cos n\theta \]  

(37)

The barred expressions for the antisymmetric case are obtained by replacing \( \cos n\theta \) by \( \sin n\theta \) and \( \sin n\theta \) by \( \cos n\theta \) in Eq. (37).

7. Numerical results and discussion

The frequency equations obtained in symmetric and antisymmetric cases given in Eqs.(27) and (29) are analyzed numerically for thermal bars of polygonal (triangular, square, pentagonal and hexagonal) cross-sections immersed in fluid. The material chosen for the numerical calculation is Zinc, whose elastic constants are given in Sharma and Sharma (2002) are

\[ c_{11} = 1.628 \times 10^{11} Nm^{-2}, \quad c_{12} = 0.362 \times 10^{11} Nm^{-2}, \quad c_{13} = 0.508 \times 10^{11} Nm^{-2}, \quad c_{33} = 0.627 \times 10^{11} Nm^{-2}, \quad c_{44} = 0.385 \times 10^{11} Nm^{-2} \]

and density \( \rho = 7.14 \times 10^3 kg m^{-3} \). The thermal properties such as thermal expansion coefficients \( \beta_1 = 5.75 \times 10^6 Nm^{-2} deg^{-1}, \quad \beta_3 = 5.17 \times 10^6 Nm^{-2} deg^{-1} \), thermal conductivities \( K_1 = 1.24 \times 10^2 Wm^{-1} deg^{-1}, \quad K_3 = 1.24 \times 10^2 Wm^{-1} deg^{-1} \), specific heat capacity \( c_v = 3.9 \times 10^2 Jkg^{-1} deg^{-1} \) and the reference temperature \( T_0 = 296 K \), and for fluid the density \( \rho_f = 1000 kg / m^3 \) and phase velocity \( c = 1500 m / sec \) are used for the numerical calculations.

The geometric relations for the polygonal cross-sections given by Nagaya (1983)

\[ R_i/b = \left[ \cos(\theta - \gamma_i) \right]^{-1} \]  

(38)

where \( b \) is the apothem. The relation given in Eq. (38) is used directly for the numerical calculation. The dimensionless wave numbers, which are complex in nature, are computed by fixing \( \Omega \) for \( 0 < \Omega \leq 1.0 \) using secant method (applicable for complex roots, Antia, 2002). The basic independent modes like longitudinal and flexural modes of vibration are analyzed and the corresponding non-dimensional wave numbers are computed. The polygonal cross-sectional bar in the range \( \theta = 0 \) and \( \theta = \pi \) is divided into many segments for convergence of wave number in such a way that the distance between any two segments is...
negligible. The computation of Fourier coefficients given in Eq. (28) is carried out using the five point Gaussian quadrature. The results of longitudinal and flexural (symmetric and antisymmetric) modes are plotted in the form of dispersion curves. The notations used in the figures namely, LmTF, FsTF and FaTF respectively denotes the longitudinal mode of vibration for thermal bar immersed in fluid, the flexural (symmetric and antisymmetric) modes of vibration of thermal bar immersed in fluid. Similarly, the notations RLmTF, and ILmTF respectively denotes the real and imaginary parts of vibration for longitudinal modes of thermal bar immersed in fluid. The 1 refer to the first mode and 2 refer the second mode and so on in all the dispersion curves.

7.1 Triangular and Pentagonal cross-sections

The triangular and pentagonal cross-sectional cylinders (Figs. 2(c) and 2(d) of Nagaya (1983), the vibration displacements are symmetrical about the x axis for the longitudinal mode and antisymmetrical about the y axis for the flexural mode since the cross-section is symmetric about only one axis. Therefore n and m are chosen as 0, 1, 2, 3… in Eq. (27) for the longitudinal mode and n, m=1, 2, 3 … in Eq. (29) for the flexural mode.

A graph is drawn for non-dimensional frequency \( \Omega \) versus dimensionless wave number \( \varsigma \) for longitudinal mode of triangular cross sectional thermal bar immersed in fluid is shown in Fig.1.

![Fig.1 Non dimension frequency \( \Omega \) versus dimensionless wave number \( |\varsigma| \) of longitudinal mode of triangular cross section thermal bar immersed in fluid](image-url)

From the Fig.1, it is observed that, as the non dimensional frequency increases, the dimensionless wave number \( |\varsigma| \) also increases. Between \( \Omega = 0.5 \) to \( \Omega = 0.6 \), the first and second modes of vibrations merges, it indicate, the transport of heat energy between the modes of vibration. A comparison is made between the non-dimensional frequencies \( \Omega \) versus real \( (\varsigma) \) and imaginary \( (\varsigma) \) parts of dimensionless wave numbers for the longitudinal modes of triangular thermal bar immersed in fluid is shown in Fig.2.
From the Fig. 2, it is observed that the displacement of heat energy from solid to fluid linearly increases on increasing frequency for the real part of wave number, whereas the imaginary part of wave number decreases, this is the proper physical behaviour of a bar/cylinder/thermal bar immersed in fluid. It is also observed that, the imaginary part of wave number tends to zero by increasing its frequency.

The dispersion curve shown in Fig. 3, is drawn between the non dimensional frequency $\Omega$ versus dimensionless wave number $|\xi|$ for flexural anti symmetric modes of triangular cross sectional thermal bar immersed in fluid. From the Fig. 3, it is observed that, the transfer of heat energy from solid to fluid medium is not uniformly distributed, shows that, the trend line have many ups and downs. At $\Omega = 0.5$, the wave number reaches its peak and then it starts to decrease.
The Fig. 4 shows that the non-dimensional frequency $\Omega$ versus dimensionless wave number $|\varsigma|$ of transversely isotropic pentagonal cross-sectional thermal bar immersed in fluid for longitudinal modes of vibration. It is observed that as the frequency increases, the non-dimensional wave number $|\varsigma|$ also increases linearly. Between $\Omega = 0.3$ and $\Omega = 0.7$, the numbers merge with each other. It shows that the heat energy transferred between the modes of vibrations, beyond that the dispersion behaves well.

A Comparison is made for a pentagonal cross sectional bar (without thermal and fluid) with the pentagonal cross sectional thermal bar and pentagonal cross sectional thermal bar immersed in fluid is shown in Fig. 5.
From the Fig.5, it is observed that, the non dimensional wave numbers are increased by increasing its frequency in all the three types of bars. Among the displacement of energy, the thermal bar leaks more energy from solid to the vacuum, and the bar immersed in fluid leaks less energy by comparing it with the other two types of bars.

7.2 Square and Hexagonal cross-sections

In case of longitudinal vibration of square and hexagonal cross-sectional bars, the displacements are symmetrical about both major and minor axes since both the cross-sections are symmetric about both the axes. Therefore the frequency equation is obtained by choosing both terms of \( n \) and \( m \) are chosen as 0, 2, 4, 6… in Eq. (27). During flexural motion, the displacements are antisymmetrical about the major axis and symmetrical about the minor axis. Hence the frequency equation is obtained by choosing \( n, m=1, 3, 5,… \) in Eq. (29).

A graph is drawn between the non dimensional frequency \( \Omega \) versus dimensionless wave number for longitudinal modes of vibration and is shown in the Fig. 6.

From the Fig. 6, it is observed that, the anti symmetric modes of vibration gets highly dispersive by comparing the flexural symmetric modes of vibrations. A dispersion curve is drawn between the non dimensional frequency \( \Omega \) versus dimensionless wave number \( |\varsigma| \) of longitudinal modes of hexagonal cross sectional thermal bar immersed in fluid and is shown in Fig. 7.
From the Fig. 7, it is observed that, the cross over points between the third and the fourth modes at $\Omega = 0.3$ and the modes 2 and 3 at $\Omega = 0.4$ and the modes 1 and 2 at $\Omega = 0.5$ indicates that there will be exchange of heat energy between the modes of vibrations.

The non-dimensional frequencies are obtained for the longitudinal modes of polygonal cross-sectional isotropic plates immersed in fluid are given in the Eq. (32). Using the Eq. (32), the non-dimensional frequencies are obtained using that a graph is drawn to compare the non-dimensional frequency of longitudinal modes vibration for triangle, square, pentagon and hexagonal cross-sectional plates immersed in fluid is shown the Fig. 8. From the figure, it is observed that the behavior of triangle and pentagon cross-sectional plates behave similar, similarly, the square and hexagonal cross-sectional plates behave similar.

### 7.3 Comparisons of the results of the bar immersed in a fluid and in vacuum

To demonstrate the difference in the results of the polygonal cross sectional thermal bar immersed in a fluid and bar in vacuum, the difference in the absolute values of wave number $|\varsigma|$ are obtained and presented in tables to study the amount of heat energy leakage from solid into fluid. Tables 1 and 2 respectively show the percentage of difference for longitudinal and flexural mode of vibrations in case of polygonal cross sections. From the Tables, it is observed that the fluid loaded system radiates energy into the surrounding fluid medium. The percentage increase in energy transfer from the solid to its surrounding environment is compared between, the cases of a solid bar in vacuum and solid bar immersed in fluid. It is noted that, the energy transfer is lesser in case, where the solid bar is immersed in fluid. The trend is similar, both in longitudinal and flexural modes of vibration for all polygonal geometric bars. That is the eigen modes in this case are referred to as leaky modes. It is clear from these results that frequency dependence of any such leaky modes is quite complex and appear to be dependent on all the physical and geometric parameters.
Fig. 8 Comparison between the frequency response of longitudinal modes triangular, square, pentagonal and hexagonal cross-sectional plates immersed in fluid

Table 1: Comparison of the non-dimensional wave numbers $\zeta$ for the transversely isotropic thermal polygonal (triangular, square, pentagonal and hexagonal) bar immersed in a fluid and for the bar in vacuum for longitudinal vibration

| Geometry | $\Omega$ | $|\zeta|$ Thermal bar in vacuum | $|\zeta|$ Thermal bar immersed in fluid | Increase in Percentage |
|----------|---------|-------------------------------|----------------------------------|------------------------|
| Triangle | 0.1     | 0.1196                        | 0.0811                           | 3.85                   |
|          | 0.3     | 0.3564                        | 0.2443                           | 11.21                  |
|          | 0.5     | 0.5927                        | 0.4116                           | 18.11                  |
|          | 0.7     | 0.8327                        | 0.5677                           | 26.50                  |
|          | 1.0     | 1.0818                        | 0.8275                           | 25.43                  |
| Square   | 0.1     | 0.1196                        | 0.0811                           | 3.85                   |
|          | 0.3     | 0.3564                        | 0.2439                           | 11.25                  |
|          | 0.5     | 0.5924                        | 0.4094                           | 18.30                  |

8. Conclusions

In this paper, the wave propagation in a transversely isotropic thermoelastic solid bar of polygonal (triangular, square, pentagonal and hexagonal) cross-sections immersed in fluid is analyzed by satisfying the boundary conditions on the irregular boundary using the Fourier expansion collocation method and the frequency equations for the longitudinal and flexural modes of vibration are obtained. Numerically the frequency equations are analyzed for the Zinc bar of different cross-sections such as triangular, square, pentagonal and hexagonal. The computed dimensionless wave numbers are plotted as dispersion curves. The problem can be analyzed for any other cross-section by using the proper geometric relation.
