Published online: 17 October 2017

#### Abstract

Two-point boundary value problems (BVPs) have numerous applications especially in the modeling of most physical phenomena. In this study, the fourth order two-point BVPs were solved by using Successive Over-Relaxation (SOR) iterative method after discretized with cubic non-polynomial spline scheme to generate its corresponding sparse linear system. Then, a numerical experiment was conducted to determine the performances of the SOR iterative method and the spline scheme in terms of iterations number, execution time and maximum absolute error at different mesh sizes. In order to assess the performances of this proposed idea, another iterative method was also conducted which is Gauss-Seidel (GS). Based on the numerical analysis, the two-point BVPs together with the cubic non-polynomial spline scheme were found to be best solved by using the SOR iterative method.

Keywords: successive over-relaxation; cubic non-polynomial spline; fourth-order two-point boundary value problem.

## 1. INTRODUCTION

This current study aims to solve for fourth-order two-point BVPs as given by Equation (1)

$$
\begin{equation*}
y^{(4)}+a_{1}(x) y^{(3)}+a_{2}(x) y^{\prime \prime}+a_{3}(x) y^{\prime}+a_{4}(x) y=f(x), x \in[a, b] \tag{1}
\end{equation*}
$$

with its boundary condition as shown in Equation (2) as follows

$$
\begin{array}{r}
y(a)=\alpha_{1}, y(b)=\beta_{1}  \tag{2}\\
y^{\prime \prime}(a)=\alpha_{2}, y^{\prime \prime}(b)=\beta_{2}
\end{array}
$$

where $a_{1}(x), a_{2}(x), a_{3}(x), a_{4}(x)$ and $f(x)$ are known functions of domain $[a, b]$ whereas $\alpha_{i}$ and $\beta_{i}$ are constants with $i=1,2$.

Equation (1) has to undergo a process lowering of order to reduce the single equation of fourth-order problem into two separated equations of second-order problems as below

$$
\begin{align*}
& v^{\prime \prime}(x)+a_{1}(x) v^{\prime}(x)+a_{2}(x) v(x)=G(x), \quad x \in[a, b] \\
& G(x)=f(x)-a_{3}(x) y^{\prime}(x)-a_{4}(x) y(x),  \tag{4}\\
& V(a)=y^{\prime \prime}(a)=\alpha_{2} \\
& V(b)=y^{\prime \prime}(b)=\beta_{2}
\end{align*}
$$

and

$$
\begin{equation*}
y^{\prime \prime}(x)=v(x) \tag{5}
\end{equation*}
$$

where

$$
\begin{equation*}
y(a)=\alpha_{1}, \quad y(b)=\beta_{1} \tag{6}
\end{equation*}
$$

The process was completely done by using simple mathematical differentiation and substitution. Then, by considering [1-5], the cubic non-polynomial spline scheme was implemented to discretize both equations (3) and (5) to generate two systems of linear equations. There are many other numerical methods which have sought wide interest among researchers and some of them are collocation method [6], adomian decomposition method [7], finite element and finite volume methods [8], finite-difference method [8], non-linear shooting method [9] and precise time integration method [10]. Nonetheless, BVPs were usually solved with three standard approaches which are shooting, finite differences and projections [11].

To make the discretization process simpler, the solution domain $[a, b]$ was divided uniformly into subintervals, $m$ as shown in Fig. 1.

Fig.1. Separation of uniform subintervals, $m=8$
where the length, $\Delta x$ of each subinterval is given as follows

$$
\begin{equation*}
\Delta x=\frac{b-a}{m}=h \tag{7}
\end{equation*}
$$

Then, Equation (3) and (5) were solved iteratively at once by using SOR iterative method by referring to [12-15]. In order to assess the performance of this proposed idea clearly in term of iterations number, execution time and maximum absolute error, GS iterative method was also conducted for comparison purpose.

In response to the vast applications of two-point BVPs as stated by [16-20] regardless of fields, it is the main focus of this present study to initiate a numerical idea in term of technique and algorithm, as well as to provide a reference for future research. To be precise, a preparation for application of spline scheme at a different degree for solving two-point BVPs of high-order with different iterative methods.

## 2. METHOD OF SOLUTION

The general function of spline which was given consideration is as follows

$$
\begin{equation*}
S(x)=Q_{i}(x), \quad x \in\left[x_{i}, x_{i+1}\right], \quad i=0,1, \cdots, n \tag{8}
\end{equation*}
$$

and the approach starts with a derivation of non-polynomial spline equations from the general function of cubic non-polynomial spline as given by Equation (9)

$$
\begin{equation*}
Q_{i}(x)=a_{i} \cos k\left(x-x_{i}\right)+b_{i} \sin k\left(x-x_{i}\right)+c_{i}\left(x-x_{i}\right)+d_{i} \tag{9}
\end{equation*}
$$

where $a_{i}, b_{i}, c_{i}$ and $d_{i}$ are constants for $i=0,1, \cdots, n$ and $k$ is the frequency for the trigonometric function in Equation (8) as $k \rightarrow 0$. Before discretized, Equation (8) was first defined into several variables as below.

$$
\begin{align*}
& Q_{i}\left(x_{i}\right)=y_{i}, \quad Q_{i}\left(x_{i+1}\right)=y_{i+1}, \quad Q_{i}^{\prime}\left(x_{i}\right)=D_{i},  \tag{10}\\
& Q_{i}^{\prime}\left(x_{i+1}\right)=D_{i+1}, \quad Q_{i}^{\prime \prime}\left(x_{i}\right)=S_{i}, Q_{i}^{\prime \prime}\left(x_{i+1}\right)=S_{i+1} .
\end{align*}
$$

By assuming the value of $y(x)$ as the exact solution, a set of non-polynomial spline equations, $S_{i}$ for $y_{i}=y\left(x_{i}\right)$ was obtained from all the segments of $Q_{i}(x)$ which passing through the points $\left(x_{i}, S_{i}\right)$ and ( $x_{i+1}, S_{i+1}$ ) as shown in Fig. 2.

Fig.2.Illustration of non-polynomial spline equations for $m=8$
Then, this discretization process ended with all the values of constant $a_{i}, b_{i}, c_{i}$ and $d_{i}$ were expressed in term of $y_{i}, y_{i+1}, D_{i+1}, D_{i}, S_{i}, S_{i+1}$ in the following form

$$
\begin{gather*}
a_{i}=h^{2} \frac{-S_{i+1}+S_{i} \cos (\theta)}{\theta^{2} \sin (\theta)},  \tag{11}\\
b_{i}=-h^{2} \frac{S_{i}}{\theta^{2}}, \\
c_{i}=\frac{y_{i+1}-y_{i}}{h}+h \frac{\left(S_{i+1}+S_{i}\right)}{\theta^{2}}, \\
d_{i}=y_{i}+h^{2} \frac{S_{i}}{\theta^{2}}
\end{gather*}
$$

where $\theta=k h \quad$ and $i=0,1,2 \ldots, N$.
However, all the constant values must be substituted in the continuity equation $Q_{i-1}^{m}(x)=$ $Q_{i}^{m}(x)$ where $m=0,1$ and has to be solved simultaneously before the general approximation equation can be formed as below
$-\left(\frac{1}{4 h}\right) y_{i-1}+\left(\frac{1}{2 h}\right) y_{i}-\left(\frac{1}{4 h}\right) y_{i+1}+h \alpha S_{i-1}+2 h \beta S_{i}+h \alpha S_{i+1}=0$
where
$\alpha=\left(\frac{1}{\theta \sin 4 \theta}-\frac{1}{4 \theta^{2}}\right), \beta=\left(\frac{1}{4 \theta^{2}}-\frac{4 \theta \cos 4 \theta}{\theta \sin 4 \theta}\right)$ and $i=0,1,2, . ., N$.
In order to eliminate all the variables $S$ in Equation (12), finite difference approach in Equation (13) composes of central finite difference, backward finite difference, and forward finite difference were used to replace all the variables.

$$
\begin{gather*}
S_{i-1}=-f_{i-1} y_{i}^{\prime}-q_{i-1} y_{i-1}+g_{i-1} \\
S_{i}=-f_{i} y_{i}^{\prime}-q_{i} y_{i}+g_{i}  \tag{13}\\
S_{i+1}=-f_{i+1} y_{i+1}^{\prime}-q_{i+1} y_{i+1}+g_{i+1}
\end{gather*}
$$

where,

$$
\begin{gathered}
y_{i}^{\prime}=\frac{y_{i+1}-y_{i-1}}{2 h} \\
y_{i-1}^{\prime}=\frac{-y_{i+1}+4 y_{i}-3 y_{i-1}}{2 h} \\
y_{i+1}^{\prime}=\frac{3 y_{i+1}-4 y_{i}+y_{i-1}}{2 h}
\end{gathered}
$$

The general approximation equation was finally obtained as given by Equation (14) as follows

$$
\begin{equation*}
a_{i} y_{i-1}+b_{i} y_{i}+c_{i} y_{i+1}=F_{i}, i=0,1,2, \ldots, n \tag{14}
\end{equation*}
$$

where

$$
\begin{gathered}
a_{i}=-\mu_{0}+\gamma\left(\frac{3 p_{i-1}}{2 h}-q_{i-1}\right)+\theta \frac{p_{i}}{2 h}-\gamma \frac{p_{i+1}}{2 h}, \quad b_{i}=2 \mu_{0}-\gamma \frac{2 p_{i-1}}{h}-\theta q_{i}+\gamma \frac{2 p_{i+1}}{h} \\
c_{i}=-\mu_{0}+\gamma \frac{p_{i+1}}{2 h}-\theta \frac{p_{i}}{2 h}+\gamma\left(\frac{3 p_{i+1}}{2 h}-q_{i+1}\right), \quad F_{i}=-\gamma f_{i-1}-\frac{\theta}{2 h} f_{i}+\gamma f_{i+1} \\
\gamma=\mu_{1} h^{2}, \quad \phi=2 \mu_{2} h^{2}, \\
\mu_{1}=\theta-\sin \theta, \quad \mu_{2}=\sin \theta-\theta \cos \theta .
\end{gathered}
$$

By using computer program, Equation (14) was used to construct a system of linear equations in a matrix form of Equation Equation(15) as below

$$
\begin{equation*}
A \underset{\sim}{y}=\underset{\sim}{F} \tag{15}
\end{equation*}
$$

where

$$
\begin{gathered}
A=\left[\begin{array}{cccccc}
a_{1} & b_{1} & & & & \\
a_{2} & b_{2} & c_{2} & & & \\
& a_{3} & b_{3} & c_{3} & & \\
& & \ddots & \ddots & \ddots & \\
& & & a_{n-1} & b_{n-1} & c_{n-1} \\
& & & a_{n} & b_{n}
\end{array}\right]_{(n \times n)} \\
\underset{\sim}{y}=\left[\begin{array}{lllllllll}
y_{1} & y_{2} & y_{3} \ldots & y_{n-1} & y_{n}
\end{array}\right]^{T}, \quad \underset{\sim}{F}=\left[\begin{array}{lllll}
F_{1}-a_{1} y_{0} & F_{2} & F_{3} \ldots & F_{n-1} & F_{n}-c_{n} y_{n+1}
\end{array}\right]^{T}
\end{gathered}
$$

Then, the SOR and GS iterative methods were conducted to solve two linear systems Equation (15) by varying the size of the matrix (128, 256, 512, 1024, 2048), so that the performance of this proposed idea can be discussed evidently.

## 3. ALGORITHM

Particularly, the derivation of the SOR iterative method starts with decomposition of the coefficient matrix, A in Equation (15) into diagonal, lower triangular and upper triangular matrices as follow

$$
\begin{equation*}
A=D+L+U \tag{16}
\end{equation*}
$$

By imposing Equation (16) into Equation (15), it yields to the SOR iteration equation in the following form

$$
\begin{equation*}
{\underset{\sim}{y}}^{(k+1)}=(1-\omega){\underset{\sim}{r}}^{(k)}+\omega(D+L)^{-1}\left(\left(-U \underset{\sim}{y}{ }^{(k)}+\underset{\sim}{F}\right)\right) \tag{17}
\end{equation*}
$$

with the optimum value of the parameter $\omega$ obtained through several iterations in range of $1 \leq \omega<2$. The selection of the $\omega$ valueis best on the smallest number of iterations it produces when used to solve for the problems.

Since the single fourth-order two-point BVPs were reduced to two separated equations of second-order problems, therefore, there are two systems of linear equations must be solved simultaneously. To do this, the first system was first iterated to get the value of function $G(x)$ which then passed to the second system in order to solve it. Even though these two linear systems were solved differently, but both still using the same general approximation Equation (14). The algorithm of the SOR iteration when solving the two systems of linear equations are presented in Table 1.

Table 1. Algorithm of SOR iterative method
i. Initialize $U_{i}^{(0)} \leftarrow 0, \varepsilon \leftarrow 10^{-10}$
ii. Assign the optimal value of $\omega$
iii. Solve the system by calculating $U_{i}^{(k+1)}$ using

$$
{\underset{\sim}{S}}^{(k+1)}=(1-\omega){\underset{\sim}{S}}^{(k)}+\omega(D+L)^{-1}\left(-U \underset{\sim}{U}{ }^{(k)}+\underset{\sim}{F}\right)
$$

iv. Check the convergence test, $\left|U_{i}^{(k+1)}-U_{i}^{(k)}\right| \leq \varepsilon=10^{-10}$.

If yes, go to step (v). Otherwise go back to step (iii).
v. Display the approximate solutions.

## 4. NUMERICAL EXPERIMENT

The numerical experiments were conducted to solve for three examples of fourth-order two-point BVPs. These three examples together with its exact solution are as follow

Example 1 [21]

$$
\begin{gathered}
y^{(4)}(x)-2 y^{\prime \prime}(x)+y(x)=-8(\exp (x)), \\
y(0)=y(1)=0, \\
y^{\prime \prime}(0)=0, \\
\mathrm{y}^{\prime \prime}(1)=-4 e
\end{gathered}
$$

with its exact solution

$$
y(x)=x(1-x) e^{x}
$$

Example 2 [21]

$$
\begin{gathered}
\left.y^{(4)}(x)-2 y^{\prime \prime}(x)+y x\right)=0, \\
y(0)=y^{\prime \prime}(0)=1 \\
y u(1)=y^{\prime \prime}(1)=e
\end{gathered}
$$

with its exact solution

$$
y(x)=e^{x} .
$$

Example 3 [21]

$$
\begin{gathered}
y^{\prime \prime}-y=-4(2 x \cos (x)+3 \sin (x) \\
y(0)=y(1)=0 \\
y^{\prime \prime}(0)=0 \\
y^{\prime \prime}(1)=2 \sin (1)+4 \cos (1)
\end{gathered}
$$

with its exact solution

$$
y(x)=\left(x^{2}-1\right) \sin (x) .
$$

## 5. RESULTS AND DISCUSSION

Based on the numerical experiments, the performance results of all examples in terms of iterations number $(\mathrm{K})$, execution time ( t ) in seconds, maximum absolute error $(\varepsilon)$ were successfully tabulated in Table 2, 3 and 4 respectively. It can be seen that as the mesh sizes increasing, the iterations number also increasing due to the accumulated round-off error occurred at every iteration. However, the main aim is to compare which method will give the best performance, thus focus should be given on the performance comparison between these two iterative methods.

Table 2. Result of performances for Example 1

|  | GS |  |  | SOR |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  |  |  |  |  |  | $\omega=1.9972$ |

By referring to all the tables as mentioned previously, it was found that SOR method performed better than GS method when solving Example 1, 2 and 3. This can be seen clearly
through the difference of iterations number, execution time and maximum absolute error at different mesh sizes which are $128,256,512,1024$ and 2048. This difference was further analyzed in percentage form so that the improvement can be evidently presented.

The SOR iterative method can be said to perform better compared to GS method when solving the fourth-order two-point BVPs, as it required lesser iteration numbers and shorter time execution in order to iterate and converge to its exact solution. In fact, by looking at the maximum absolute error, it has higher accuracy compared to GS. As to complement the tabulated results of performance, Fig.1, Fig. 2 and Fig. 3 were presented to clarify that the problems are best solved by using SOR method. All the values of the percentage decrease were tabulated in Table 5, 6 and 7.

Table 5. Percentage decrease for Example 1

|  | Improvement of SOR Over GS (\%) |  |  |
| :---: | :---: | :---: | :---: |
| Size | $\mathbf{K}$ | $\mathbf{t}$ | $\varepsilon$ |
| 128 | $97.96 \%$ | $22.67 \%$ | $1.31 \%$ |
| 256 | $98.96 \%$ | $75.68 \%$ | $26.44 \%$ |
| 512 | $99.45 \%$ | $88.94 \%$ | $61.69 \%$ |
| 1024 | $99.69 \%$ | $95.84 \%$ | $98.15 \%$ |
| 2048 | $99.83 \%$ | $98.61 \%$ | $99.84 \%$ |

Table 6. Percentage decrease for Example 2

|  | Improvement of SOR Over GS (\%) |  |  |
| :---: | :---: | :---: | :---: |
| Size | $\mathbf{K}$ | $\mathbf{t}$ | $\varepsilon$ |
| 128 | $97.94 \%$ | $30.19 \%$ | $10.85 \%$ |
| 256 | $99.58 \%$ | $78.79 \%$ | $21.46 \%$ |
| 512 | $99.74 \%$ | $94.88 \%$ | $20.96 \%$ |
| 1024 | $99.88 \%$ | $98.77 \%$ | $93.71 \%$ |
| 2048 | $99.93 \%$ | $99.62 \%$ | $99.61 \%$ |

Table 7. Percentage decrease for Example 3

|  |  | Improvement of SOR Over GS (\%) |  |
| :---: | :---: | :---: | :---: |
| Size | $\mathbf{K}$ | $\mathbf{t}$ | $\varepsilon$ |
| 128 | $98.29 \%$ | $42.64 \%$ | $3.66 \%$ |
| 256 | $99.09 \%$ | $67.22 \%$ | $37.85 \%$ |
| 512 | $99.51 \%$ | $91.69 \%$ | $90.89 \%$ |
| 1024 | $99.73 \%$ | $96.71 \%$ | $99.42 \%$ |
| 2048 | $99.85 \%$ | $99.22 \%$ | $99.97 \%$ |

It should be noted that the percentage decrease was considered as an improvement of SOR method over GS method and was calculated by setting the performance of GS as an initial value, whereas SOR as the final value and the negative sign of percentage decrease was omitted from the graph.

Fig.1. Percentage decrease for Example 1

Fig.2. Percentage decrease for Example 2

Fig. 3. Percentage decrease for Example 3
By observing these graphs of percentage decrease from Fig.1, Fig. 2 and Fig.3, the performances of SOR method can be seen to have a notable improvement in terms of iterations number followed by the execution time and maximum absolute error. As the matrix size increasing, the performances of SOR method are improving over GS method for every increment of mesh sizes. This indicates that the non-polynomial spline scheme together with the SOR method can cope with the accumulated round-off error better than GS method. Thus,
it can be stated that SOR method gives better performance especially in term of iterations number.

For future work, it is highly recommended to extend this study for solving high order two-point BVPs with different degree of spline such as quartic, quintic and so on by referring to [1-5], [14-15, 22].

## 6. CONCLUSION

The cubic non-polynomial spline approximation equations were successfully derived from the single function of cubic non-polynomial spline general function. The performances in term of iterations number, execution time and maximum absolute error were analyzed by solving several examples of fourth-order two-point BVPs together with its exact solution by using SOR and GS iterative methods. Then, it was found that the SOR iterative method is superior compared to GS iterative method for different mesh sizes $(128,256,512,1024,2048)$ and can be seen from the improvement through the percentage decrease of its respective iterations number, execution time and maximum absolute error. Hence, it can be concluded that the fourth-order two-point BVPs together with the cubic non-polynomial spline scheme are best solved by using SOR iterative method compared to GS iterative method.
