Prevalence of Dyslipidaemia Amongst Apparently Healthy Staff of a Tertiary Hospital in Benin City.

EDO A E AND ENOFE C O

Abstract
Dyslipidaemia (DL) is an independent and modifiable risk factor for cardiovascular disease (CVD) which appears to be on the increase in Nigeria due to the adoption of 'westernised' lifestyles by Nigerians. CVD is associated with significant premature morbidity and mortality. Other risk factors for CVD include hypertension, obesity and diabetes mellitus. Screening for DL is often overlooked in apparently healthy Nigerians due to the fact that there is little public awareness on DL, which is largely asymptomatic. The aim of this study is to determine the serum lipid profile of apparently healthy staff of University of Benin Teaching Hospital (UBTH), Benin City. Consenting staff of UBTH who were apparently healthy were recruited for the study. Data extracted included the patient’s age, sex, body mass index, weight, height, waist circumference, blood pressure and fasting lipid profile. Two hundred and two females and 102 males were included in the study. High-density lipoprotein cholesterol dyslipidaemia was found in 12.9% of female subjects and in 10.8% of male subjects. Total cholesterol dyslipidaemia, low-density lipoprotein cholesterol dyslipidaemia and triglyceride dyslipidaemia were found in 51.0%, 26.3% and 4.9% of the subjects respectively. There was no significant gender difference in the lipid profile of the study subjects. There is a high prevalence of total cholesterol dyslipidaemia and low-density lipoprotein cholesterol dyslipidaemia among apparently healthy staff of UBTH. Pre-employment and annual lipid profile screening should be instituted for early diagnosis and treatment of dyslipidaemias in order to minimize the risk of cardiovascular events.

Introduction
Cardiovascular disease (CVD) due to atherosclerosis of the arterial vessel wall and to thrombosis is the leading cause of premature mortality and morbidity in the developed countries of Europe and the United States\(^1\). Atherosclerosis causes a reduction of blood flow and inadequate delivery of oxygen and nutrients to various organs thereby resulting in myocardial infarction, stroke or peripheral vascular disease depending on the end-organ affected. The narrowing of the vessel wall is due to lipid deposition (derived from plasma lipoproteins and elevated plasma cholesterol) and cell proliferation. The risk factors for CVDs include cigarette smoking, lack of exercise, elevated blood pressure, type 2 diabetes mellitus, male gender, obesity and dyslipidaemia (DL)\(^1\). Dyslipidaemia was previously thought to be uncommon in Nigeria\(^4,5\). The
“westernization” of the Nigerian populace has increased the risk for the development of DL and other risk factors for CVDs. There has been more public enlightenment on hypertension, diabetes mellitus than on dyslipidaemia as a risk factor for CVD. Despite its importance as an independent but modifiable risk factor for CVD, dyslipidaemia is seldom screened for among non-diabetic Nigerians. The aim of this study was to determine the lipid profile of a select group of apparently healthy Nigerians (staff of the University of Benin Teaching Hospital) who are on regular income (salaried) as they are more likely to maintain a “westernized” lifestyle than Nigerians in the rural communities.

**Subjects and Methods**

All consenting apparently healthy staff of the University of Benin Teaching Hospital was consecutively recruited for the study after detailed explanation of the aim of the study to them. All participants gave informed consent. Data documented included the patient’s age, sex, body mass index (BMI), blood pressure, use of antihypertensive agents, fasting lipid profile (total cholesterol, triglyceride, high density lipoprotein cholesterol, low density lipoprotein cholesterol) and anthropometric indice including: height, weight, and waist circumference (WC) which was measured at midpoint between the lower rib margin and the iliac crests while the hip circumference was measured at the maximal point of the buttock (through both greater trochanters). Approval for this study was obtained from the Ethics Committee of the Hospital.

Persons known to have diabetes mellitus (which is regarded as a coronary heart disease equivalent) or who were on lipid-lowering drugs were excluded from the study.

Statistical analysis was carried out using the Statistical Package for Social Sciences (SPSS) version 16. The mean ± SD values were calculated for all the variables. Comparison of means was done using t-test for continuous data and Chi-square test for categorical data. Level of statistical significance was set at p < 0.05.

**Definition of terms**

Using World Health Organization criteria, dyslipidaemia was present if subject was receiving statin treatment or had plasma triglycerides (TG) ≥ 150mg/dL (≥ 1.7 mmol/L), high density lipoprotein cholesterol (HDLc): men < 35mg/dL (0.9 mmol/L); women < 39mg/dL (1.0mmol/L).

Other dyslipidaemia were defined as follows: Total cholesterol (TC) ≥ 200mg/dL (5.18mmol/L) and low density lipoprotein cholesterol (LDLc) ≥ 150mg/dL (3.89mmol/dL)

Hypertension was present if systolic blood pressure ≥ 140mmHg or diastolic blood pressure ≥ 90mmHg, or if subject was on antihypertensive medication.

Abdominal obesity was defined as WC > 88cm in women and WC > 102 cm in men while generalized obesity was BMI > 30kg/m² in both gender.

**Results**

The study group consisted of 304 Nigerians who work in UBTH. The mean age of the study subjects was 45.11 ± 9.53 years (min-max 23-65 years). Among the study subjects, 202 (66.4%) were females, 87 (28.6%) were obese, 104 (34.2%) were overweight, 70 (23%) were hypertensive and 176 (57.9%) had dyslipidaemia.

The characteristics of the study subjects are summarized in Table I. The common

types and frequency of dyslipidaemia in
the study subjects are summarized in
Figure 1. Total cholesterol DL and LDLc
dyslipidaemias were commonest types
found in our study subjects. There was no
significant difference in mean serum lipid
levels (Table 2) between male and female
subjects. There was a significant
correlation between TC and BMI (r = 0.18,
p = 0.002) and between LDL and BMI (r =
0.15, p = 0.01). Systolic blood pressure and
diastolic blood pressure were significantly
higher in the male subjects than in female
subjects while waist circumference and
body mass index were larger in the female
subjects.

Discussion
This study documented a high prevalence
of dyslipidaemia (57.9%) which is much
higher than the 4.0% documented in the
National Non-communicable Disease
Survey. The commonest types of
dyslipidaemia we found were elevated
total cholesterol and elevated LDL
cholesterol dyslipidaemias. High plasma
cholesterol levels are linked with increased
risk for CVD. The Multiple Risk Factor
Intervention Trial showed that there is
increased risk at levels above 5.2mmol/L
(200mg/dL). The frequency of elevated
total cholesterol dyslipidaemia was higher
in our study than in the report by Odenigbo
et al (elevated total cholesterol DL: 51% vs
23%) while the frequency of elevated LDL
cholesterol and reduced HDL cholesterol
DL were lower (elevated LDL cholesterol:
26.3% vs 51% and reduced HDL
cholesterol DL: 14.8% vs 60%).

The mean total cholesterol of 5.28±1.20
mmol/L, HDL cholesterol of 1.62±0.60
mmol/L and LDL cholesterol levels of
3.21±1.16 mmol/L found in our study
subjects were generally higher than those
of other Nigerian studies except that of
Osuji et al who found a mean total
cholesterol level that was comparable to
our finding (5.29±1.76 mmol/L vs 5.28±
1.20 mmol/L). There was no significant
gender difference in the lipid profile of our
subjects which is similar to findings in
previous Nigerian studies. The mean
LDL cholesterol of 3.21±1.16 mmol/L and
triglyceride of 1.07±0.37 mmol/L levels in
our study were less than those in
Caucasians.

The reasons for the higher lipid levels in
our study subjects compared to those in
previous studies in Nigerians are not
known with certainty as Nigerians living in
the Southern part of the country consume
diets with similar fat and carbohydrate
contents. Palm oil which is rich in
saturated fatty acids is commonly
consumed in this region. Lack of physical
activity and consumption of diets high in
carbohydrate and fat have been
documented as contributing factors to the
poor health status of some affluent
Nigerians. Urbanization in the developing
countries has resulted in emergence of fast
food eateries where high dense foods are
sold; improved transportation systems and
use of computers which encourage
sedentary lifestyles. This pattern of
behavior encourages development of
obesity which occurred in 28.6% of our
study subjects. Public enlightenment on
healthful nutrition and the benefits of
regular exercises is needful. Studies have
shown beneficial effects of low fat diet and
regular exercise on lipid profile.

Drugs are available for the treatment of
dyslipidaemia. These include the statins and
the fibric acids. These drugs are able
to lower elevated total cholesterol,
triglyceride and LDL cholesterol levels and
raise HDL cholesterol. Treatment of
dyslipidaemia has been shown to lower
mortality due to CVD. Elevation of ≥ 7.5% in HDL-c, together with a reduction in LDL-c to a target of < 2.0 mmol/L was the minimum requirement for plaque regression.

In conclusion, our study showed that elevated total cholesterol and elevated LDL-cholesterol dyslipidaemias were common among apparently healthy Nigerians working at UBTH. The combination of elevated total cholesterol and elevated LDL-cholesterol dyslipidaemias, obesity and hypertension among the hospital staffs put them at increased risk of cardiovascular events. The Management of the hospital should institute pre-employment and annual serum lipid profile screening for early diagnosis and treatment of dyslipidaemias in order to minimize the risk of cardiovascular events.
