Morphological spectrum of non-neoplastic lesions of the uterine cervix in Warri, South-South, Nigeria

FN Nwachokor, GD Forae

Department of Pathology, Delta State University Teaching Hospital, Abraka, 1Department of Pathology, University of Benin Teaching Hospital, Benin City, Nigeria

Abstract

Background: The uterine cervix is a gateway to several non-neoplastic and neoplastic gynecological lesions. Most of these non-neoplastic lesions are commonly found in women of reproductive age. These lesions constitute a source of morbidity and mortality in women worldwide hence the need to analyze them to provide a baseline data of the pattern of these lesions in our local environment.

Objective: The purpose of this study is to determine the frequency and morphological patterns of non-neoplastic cervical lesions at the central hospital, Warri, Nigeria.

Materials and Methods: All uterine cervical biopsies received at the Department of Pathology, Central Hospital, Warri over a 7 year period (January 2005-December 2011) were the specimens for this study. Slides were retrieved from the archives of the Department of Pathology. Where necessary, new sections were made from formalin fixed, paraffin embedded blocks.

Results: A total of 176 cervical specimens were received in the Pathology Department during this period. Of these, 56.3% were benign lesions while 43.7% were malignant. Among the benign cases, non-neoplastic lesions accounted for 92.9% of benign cervical lesions. The age range of non-neoplastic cervical lesions was 20 to 89 years with a mean age of 54.9 ± 4.6 years. The peak age incidence of non-neoplastic cervical lesion was 40-49 years which accounted for 33.7%. Inflammatory lesions and tumor-like lesions accounted for 59.8% and 40.2% of non-neoplastic cervical lesions respectively. Among the inflammatory lesions, chronic non-specific cervicitis was the most commonly encountered lesion constituting 72.2% of all inflammation. Human papilloma virus (HPV) cervicitis with koilocytic changes accounted for 14.5% of all inflammatory lesions.

Conclusion: Inflammatory lesions were the most frequent non-neoplastic cervical lesions. These lesions therefore account for significant amount of gynecological problems in our environment. Adequate cervical screening with follow up histological biopsies is a relevant tool in diagnosing them to enhance early detection of premalignant and malignant cervical lesions.

Key words: Benign, cervical lesions, non-neoplastic, diagnosis, histopathology

Date of Acceptance: 06-Sep-2012

Introduction

Non-neoplastic cervical lesions cut across all age groups amongst women but are more commonly seen in sexually active women. These lesions include inflammatory and tumor-like non-neoplastic lesions. Majority of non-neoplastic lesions are inflammatory in nature.[1,2] Inflammatory lesions of clinicopathological importance are acute cervicitis, chronic cervicitis and chronic granulomatous cervicitis.[1,2] These can result from both infective and non-infective aetiology. Infective causes of acute and chronic cervicitis include a wide
A spectrum ranging from bacterial, viral, protozoan and fungi microorganisms commonly encountered in sexually transmitted infections (STIs) and urinary tract infections (UTIs). Studies have shown that chronic granulomatous cervicitis is mostly caused by tuberculosis. Sexual transmitted viruses include human papilloma virus (HPV) and herpes simplex virus. HPV cervicitis is a causal risk factor for condylomata acuminatum, pre-invasive cervical intraepithelial neoplasia (CIN I, II, III) and eventually cervical cancer.

Tumor-like non-neoplastic cervical lesions according to the World Health Organization include endocervical hyperplasia, endometriosis, nabothian cyst, endocervical polyps. Study done by Pallipady et al. have shown that polypoidal endocervicitis, squamous metaplasia, micro glandular hyperplasia, accounted for 29.3%, 73.4%, 2.6% of all non-neoplastic lesions of the cervix respectively.

The aim of this study is to establish the prevalence and histological types of non-neoplastic cervical lesions of the cervix in Delta State, Nigeria. It is hoped that data derived from this research will be useful in the management of these lesions and as well serve baseline data for further research.

Materials and Methods

All uterine cervical biopsies received at the Department of Pathology, Central Hospital, Warri over a 7 year period from January 2005-December 2011 were the materials for this study. These specimens were sent from the Obstetrics/Gynecology and Consultant’s out patient clinic of this hospital, and other hospitals in the Warri metropolis and all over Delta State of Nigeria. Clinical and demographic data including age, sex, clinical history, diagnosis was obtained from surgical day books, request cards and case files. Slides were retrieved from the archives of the Department of Pathology. Where necessary new sections were made from formalin fixed, paraffin embedded blocks and stained with Hematoxylin and Eosin. Where necessary special stains were used to further characterize cervical lesions. These lesions are classified using the World Health Organization (W.H.O.) criteria

Data obtained were analyzed using the SPSS version 16 statistical package.

Results

Demographic analysis

During this seven year period, a total of 176 cervical specimens were received in the Pathology Department. Of these, 99 cases (56.3%) were benign lesions while 77 cases (43.7%) were malignant. Among the benign cases, 92 were non-neoplastic accounting for 92.9% of benign cervical lesions.

Table 1 shows the age distributions of non-neoplastic cervical lesions. The age range of non-neoplastic cervical lesions was 20 to 89 years with a mean age of 54.9 ± 4.6 years. The peak age incidence was 40-49 years accounting for 33.7% of non-neoplastic cases. Only 7 cases (7.6%) and 5 cases (5.5%) occurred before 30 years and after 70 years respectively.

Clinicopathological Analysis

Table 2 shows the histological types of non-neoplastic cervical lesions. Inflammatory lesions accounted for 55 cases (59.8%) of non-neoplastic cervical lesions. Thirty seven cases (40.2%) were tumor-like non-neoplastic cervical lesions. Among the inflammatory lesions, chronic non-specific cervicitis was the most commonly encountered lesion constituting 40 cases (72.2%) of all inflammation. Our study show that 75.2% of all chronic non-specific cervicitis occurred in the 4th to 6th decades of life.

Human papilloma virus (HPV) cervicitis with koilocytic changes accounted for 14.5% of all inflammatory lesions. The second most common lesion was endocervical polyps accounting for 15 cases (16.3%) of non-neoplastic cervical lesions. Ectropion with squamous metaplasia was rare accounting for 11.1% of non-neoplastic cervical lesions. Endocervical hyperplasia, nabothian cyst, and endometriosis, were extremely uncommon lesions accounting for (n = 4;
lesions. The reason for this is that the cervix is a gateway to pregnancy, delivery and post-partum. Studies have showed that sexually transmitted infections implicated in cervicitis are recurrent and or persistence. Most cases are treated empirically by physicians or by self-medication. Therefore only few difficult cases would present at the gynecological clinic for proper evaluation when symptoms are recurrent and or persistence.

In this study, the peak age range of non-neoplastic cervical lesions was 40-49 years accounting for 33.7%. This finding is similar to recent work done by Omontyi-Esan et al. where chronic non-specific cervicitis accounted for 82% of all non-neoplastic lesions. The reason for this is that the cervix is a gateway to reproduction and sexual intercourse and hence can be prone to STIs and UTIs during intercourse, conception, pregnancy, delivery and post-partum. Studies have showed that sexually transmitted infections implicated in cervicitis include Neisseria gonorrhoeae, chlamydia trachomatis and staphylococcus aureus in women of developing countries. Thus it accounted for 10%, 7.7% and 7% in Kenya, Ghana and Gambia respectively. Reports have it that the frequency of chronic cervicitis in sexually active adolescent girls is 10.5% in Nigeria. In our study chronic non-specific cervicitis occurred between the age range of 20-79 years with a peak incidence at the 5th decades of life. No case was seen before menarche. This is similar to previous reports by Craig and Lowe. The reason being that most girls are not sexually active before menarche. However in this study chronic cervicitis is a common phenomenon in post-menopausal women. This finding also corroborate previous reports by other researchers. The reasons for this are linked to sexual activities, reduction in immunity, use of replacement hormone therapy.

Studies have shown that HPV cervicitis is on the increase worldwide. Modern diagnostic techniques including polymerase chain reactions, HPV genotyping, In situ hybridization and molecular studies have increased the specificity of this diagnosis. The frequency of HPV cervicitis, particularly high risk biotypes that usually result in cervical cancer varies world-wide. The prevalence of chronic cervicitis with koilocytic changes of HPV infection in this study accounted for 14.6% of all cervicitis. This occurred in sexually active women between the ages of 30 to 59 years in this study. Our finding is in keeping with reports from Argentina where HPV accounted for 15% of sexually active women between the ages of 15 to 65 years. Nevertheless, this finding is slightly at variance with the prevalence of HPV positivity of 26.3% in Ibadan. The reason for this variation is attributed to the different methods used. Other studies from Africa also supported the high prevalence of HPV cervicitis in Sub-Saharan Africa. Studies done in Uganda reported 17% prevalence of HPV cervicitis. Although the method used (Hybrid capture assay II) is more sensitive, the findings are lower than these reported values. The reason attributed to this is that most cases in our environment go unreported. In addition, it is also important to note that most cases are treated empirically by physicians or by self-medication. Therefore only few difficult cases would present at the gynecological clinic for proper evaluation when symptoms are recurrent and or persistence.

In this study, the peak age range of non-neoplastic cervical lesions was 40-49 years accounting for 33.7%. This finding is similar to previous reports from Ile-Ife where its peak age of 40-49 years accounting for 34.7%. Our findings have showed that among the non-neoplastic cervical lesions biopsied, 59.8% were associated with features of cervicitis. Thus, it constitutes the highest percentage of non-neoplastic cervical lesions in our environment. This report again is similar to previous studies by researchers where cervicitis accounted for 80% and 98% respectively. However our report is at variance with reports by some researchers from other parts of the world where malignant cervical lesions were more common than benign lesions. The reason for this variation may be partly due to differences in geo-ethnic variation, inadequate cancer register in our locality and the fact that most cancer patients seek alternative/trado-medical therapy hence most cancer cases are not reported.

The peak age range of non-neoplastic cervical lesions was 40-49 years accounting for 33.7%. This finding is similar to previous reports from Ile-Ife where its peak age of 40-49 years accounting for 34.7%. change that cut across all age group and is a common microscopic finding and is in keeping with previous report by Pallipady. Endocervical hyperplasia was a less common finding which accounted for 4% of non-neoplastic cervical lesions with prevalence in the 5th decades of and is usually an incidental finding. Our findings are similar to reports by Pallipady et al. where this lesion was seen in 4.3% of non-neoplastic cervical biopsies.

**Conclusion**

In this study, cervicitis including HPV cervicitis was the most common non-neoplastic cervical lesions. This constitutes a scourge of morbidity and mortality if not properly diagnosed and managed. Adequate cervical screening with follow up histological biopsies is a relevant tool in diagnosing them to enhance early detection of premalignant and malignant cervical lesions.
