Summary: Consumption of extracts of Hibiscus sabdariffa (family: malvaceae) during pregnancy has been shown to cause maternal malnutrition which has been linked to various adverse conditions like increased postnatal weight gain, delayed puberty onset and elevated body weight and body mass index at onset of puberty in the female offspring. The present study was designed to investigate the possible mechanism underlying this. Eighteen in-bred pregnant Sprague-Dawley rats were on day 1 of pregnancy, randomly divided into three groups of six animals each. Group A (control) was given tap water to drink. Group B was given 0.6g extract/100ml while Group C was given 1.8g extract/100ml as their drinking solution. All groups received normal rat chow and their drinking solution ad libitum. Fluid and food intake and dam weights were measured daily throughout pregnancy. On gestational day 18, blood sample was withdrawn from each rat for estimation of plasma Na ion and corticosterone levels. On the day of delivery, the solutions of the extracts of Hibiscus sabdariffa were withdrawn and replaced with tap water. After 21 days, the pups were weaned to tap water and food ad libitum. Pups weight and age and body mass index at onset of puberty were measured. The results of the present study showed that the increased postnatal weight gain, delayed puberty onset and elevated body mass index at onset of puberty in the offspring of rats that consumed HS during pregnancy was associated with elevated maternal plasma Na ion and corticosterone levels during pregnancy.

Keywords: Hibiscus sabdariffa; delayed puberty onset; rat offspring

Introduction
Extracts of Hibiscus sabdariffa (HS) (family: malvaceae) are widely believed in folk medicine to be effective in the treatment of a variety of ailments (Perry, 1980; Watt et al., 1962; Oliver, 1960). The effectiveness of HS in the treatment of these ailments have been attributable to the various constituents of HS like flavonoids, anthocyanins, organic acids, Na+, vitamins A and C and Fe (Fuleki and Francis, 1968; Clydesdale, 1979; Duke and Francis, 1973; Morton, 1987; Daffalah and al-Mustafa, 1996; Appel, 2003; Adigun et al., 2006). Zobo drink, a sweetened beverage made from the aqueous extract of HS, is commonly produced, sold and consumed by Nigerians of all ages (irrespective of gender and physiologic state), not necessarily for its medicinal properties, but as a substitute for carbonated drinks or fruit juices because of the immense cost difference and the ready availability of HS.

We have earlier shown that rats given aqueous extract of HS to drink throughout pregnancy drank less fluid and consumed less food (Iyare and Adegoke, 2008a,b,c). The effect of reduced maternal food consumption during pregnancy on the developmental outcome of the offspring is well known. For example, maternal malnutrition during pregnancy has been linked to various adverse conditions like hypertensive, metabolic and reproductive disorders in the offspring in adult life (Armitage et al., 2005a,b; Gluckman and Hanson, 2004; Barker et al., 1993).

We have also shown that the offspring of rats given aqueous extract of HS to drink throughout pregnancy have increased postnatal weight gain, delayed onset of puberty and elevated body weight and body mass index at onset of puberty (Iyare and Adegoke, 2008a,b) through mechanism that was not clear. The present study was designed to investigate the possible mechanism by which maternal consumption of aqueous extract of HS during pregnancy mediated the observed effects in the offspring.

Materials and Methods
Experimental animal
Eighteen in-bred virgin female Sprague-Dawley rats aged between 10-12 weeks and weighing 125±5.5g (mean±SEM) with two consecutive regular 4-day estrus cycle were used for this study. These rats were housed individually in cages under standard environmental conditions. The estrous cycles were monitored and male rats of proven fertility were introduced into the cages of the female rats that were expected to get into the estrous phase within 12 hours to allow for mating. Day 1 of pregnancy was taken as the day sperm were seen in the vaginal smear of the rats. On day 1 of pregnancy, animals were divided randomly into three groups of six animals each. Group A (control)
was given tap water to drink. Group B was given 0.6g-extract/100ml while Group C was given 1.8g-extract/100ml as their drinking solution. All groups received normal rat chow and their drinking solution ad libitum. Fluid and food intake and dam weights were measured daily throughout pregnancy and at delivery.

On the day of delivery, the HS solutions were withdrawn and replaced with tap water. Each dam in each group was allowed 9 pups to nurse throughout the lactational period so as to eliminate the effect of undernutrition or overnutrition of some of the pups. After 21 days, the pups were weaned to tap water and thereafter, the female pups were kept in groups of three per cage. Pups’ weights were recorded at birth, weaning and weekly thereafter till onset of puberty. Pubertal development starts soon after weaning, so from gestational day 30 onwards, the young female rats were inspected daily for vaginal opening since onset of puberty is defined as the age (in days) at which vaginal opening occurs (Engelbregt et al., 2000). At onset of puberty, age, body weight, body length and body mass index were recorded.

Flame photometry and radioimmunoassay:

On gestational day 18, blood sample was withdrawn from the orbital sinus of each rat in each group. The blood sample was then put in a heparinised tube and centrifuged. The sodium ion content of the plasma was assessed by flame photometry and the corticosterone level was assayed by radioimmunoassay.

Extraction procedure:

Mature dry dark-red calyces of HS were purchased from a local market in Lagos, Nigeria and authenticated by Mr T.I. Adeleke of the department of Pharmacognosy, University of Lagos, Nigeria where a voucher specimen number PCG H455 was deposited. The extraction procedure used in our laboratory was as described previously (Iyare and Adegoke, 2008a,b). Briefly, 30g of the dry petals of HS was brewed in 400ml of boiled tap water for 45min. The resulting decoction was filtered and evaporated to dryness giving a dark red powder (yield 48.87%). 0.6g and 1.8g of the dark red powder were weighed and dissolved in 100ml of tap water and then given to groups B and C respectively as their drinking solution.

Statistical analysis:

The Student’s t-test for paired data was used to analyze data from the same group of rats. For data comparison between the three groups, the one way analysis of variance (ANOVA) was used followed by a post-hoc Student’s Newman-Keuls test. P<0.05 was taken as statistically significant.

Results

Maternal Fluid and Food intake

There was a significant decrease in maternal fluid and food consumption in each trimester in dams that consumed HS (HS dams) during pregnancy (Tables 1 and 2). There was no significant difference in the fluid and food consumption between the two groups of HS dams except in the second trimester when the fluid and food consumption were significantly lower in the 1.8g/100ml group.

HS = Hibiscus sabdariffa, Control = tap water (no HS). N = 6 each. * = P<0.05 vs Control, ′ = P<0.05 vs Control and 0.6g/100ml. Values are expressed as Mean ± SEM.

Weight gain during pregnancy

There was a significantly reduced weight gain in the 1\textsuperscript{st} trimester of pregnancy in the HS dams compared with the control dams (Table 3). In the 2\textsuperscript{nd} trimester, only the HS dams in the 1.8g/100ml group had a significantly reduced weight gain compared with the control dams. There was no
difference in weight gain between the 1st and 2nd trimesters among the three groups except in the 0.6g/100ml group where the weight gain in the 2nd trimester was significantly higher than that of the 1st trimester. There was no difference in weight gain among the three groups in the 3rd trimester. The weight gain in the 3rd trimester in the three groups was significantly higher than the weight gain in the 1st and 2nd trimester.

**Plasma Na⁺ and corticosterone concentration**

There was a significant increase in plasma Na⁺ and corticosterone concentration in the HS groups compared with the control group (Table 4). The effect of HS on corticosterone concentration appeared to be dose-dependent since the level of corticosterone in the dams in the 1.8g/100ml group was higher than that in the 0.6g/100ml group.

**Offspring birth weight and age, body weight, body length and BMI at onset of puberty**

The birth weight of the offspring in the HS groups was significantly higher than that in the 0.6g/100ml group. Offspring birth weight and age, body weight, body length and BMI at onset of puberty are shown in Table 5. The offspring of the HS groups was significantly delayed onset of puberty coupled with elevated body weight, body length and body mass index.

**Discussion**

The results of the present study showed that rats that consumed HS during pregnancy (HS dams) had decreased fluid and food consumption, decreased pregnancy weight gain and increased plasma Na⁺. This is in agreement with several other reports (Mojiminiyi et al, 2000; Orisakwe et al, 2004; Ojokoh, 2006; Iyare and Adegoke, 2008a,b,c).

Since maternal malnutrition during pregnancy has been shown to result in lower birth weight offspring (Barker, 2000; Seckl, 1998; Philips et al, 1998; Lesage et al, 2001; Fowden and Forhead, 2004), the reduced maternal food intake induced by HS consumption in this study, surprisingly, did not result in low birth weight offspring. This may be due to a variety of reasons. Firstly, the developing foetuses of the HS dams may have recruited adaptive mechanisms to protect their growth (Gluckman and Hansen, 2004a,b) and/or the malnutrition in the HS dams that commenced early in pregnancy, may have caused placental development that favoured increased nutrient delivery to the developing foetuses (Woodall et al, 1996; Ogerby et al, 2002; Fowden et al, 2006). Thirdly, the constituents of HS may have directly influenced the growth of the foetuses. For example, vitamin C (Jain et al, 2008; Wu et al, 2008; Yajnik, 2006), vitamin A and Fe (Ceesay et al, 1997; Christian et al, 2003; Yajnik, 2006) and flavonoids (Hilakivi-Klarke et al, 1998) have been shown to have direct growth promoting effect. The elevated glucocorticoid level observed in this study may be due to the osmotic (and the accompanying nutrient stress) stress in the HS dams as a result of the HS-induced increase in plasma Na⁺ concentration (Mojiminiyi et al, 2000; Iyare and Adegoke, 2008b).

For most of pregnancy, the concentration of glucocorticoids in the foetus is low and foetal glucocorticoids are derived from the mother down a concentration gradient through the placenta. This transplacental concentration gradient is maintained by the enzyme 11β-hydroxysteroid dehydrogenase type-2 (11βOHSD-2) that converts the active glucocorticoids, cortisol and corticosterone, to their inactive metabolites (Seckl, 2001). This enzyme, therefore, is a key factor in limiting foetal exposure to maternal glucocorticoids. Its placental activity is regulated by nutritional and endocrine factors (Clarke et al, 2002; Seckl, 2001). Thus, it follows that increased foetal glucocorticoid exposure, therefore, occurs due to increased maternal glucocorticoid levels, decreased placental 11βOHSD-2 activity or increased glucocorticoid output by the foetal adrenal.
Consumed Dose of HS have been shown to have major effects on tissue accretion when their concentrations are elevated beyond the normal physiological levels (Seckl, 2001; Jensen et al, 2002; Guo and Reidenberg, 1998; Zhang and Smith and Waddel, 2002; 2003), the elevated levels of leptin and glucocorticoids have been shown to inhibit the activity of 11βOHSD-2 (Wand et al, 2002; Guo and Reidenberg, 1998; Zhang and Wang, 1997; Lee et al, 1996). This greatly reduces the conversion of the active glucocorticoid to the inactive form and thus increases the level of glucocorticoid reaching the foetus.

Glucocorticoids have been shown to inhibit tissue accretion when their concentrations are elevated beyond the normal physiological levels (Seckl, 2001; Jensen et al, 2002). They have also been shown to have major effects on the differentiation of a wide range of tissues including the lungs, liver, kidneys, muscle, fat and gut (Fowden et al, 1998). They stimulate morphological and functional changes in these tissues and activate many of the biochemical processes which have little or no function in utero but which are essential for survival postnatally (Fowden et al, 1998). Glucocorticoids, therefore, signal adverse intrauterine conditions and adapt fetal development to ensure the maximum chances of survival both in utero and at birth. Since glucocorticoids have been shown to inhibit transplacental leptin flux (Sugden et al, 2001; Smith and Waddell, 2002; 2003), the elevated plasma glucocorticoid level observed in HS dams in this study may have reduced the amount of leptin reaching the foetus from the mother. Leptin plays a significant role in the growth and development of the foetus (Hassink et al, 1997; Ashworth et al, 2000; Yamashita et al, 2001; Smith and Waddell, 2002; 2003) and since in the fed state, circulating glucocorticoids have been shown to inhibit the activity of 11βOHSD-2 (Wand et al, 2002; Guo and Reidenberg, 1998; Zhang and Smith and Waddel, 2002; 2003). Red sorrel, Hibiscus sabdariffa calyx aqueous extract (zobo) in Wistar albino rats. Afr. J. Med. Med. Sci., 35: 73-77.

From the present study therefore, it can be concluded that the observed increase in postnatal weight gain and the delay in the onset of puberty coupled with elevated BMI in the female offspring of HS dams may have been due to overexposure to glucocorticoids in utero following increased maternal glucocorticoid level induced by HS consumption.
