Abstract

Tea is the most common beverage after water. It is extracted from the leaves of Camellia sinensis (family: Theaceae). It is consumed in different forms, namely, oolong, green, black and Ilex tea depending on post-harvest treatment and chemical components. Being rich in natural antioxidants, tea is reported to be used in the management of colon, esophageal, and lung cancers, as well as urinary stone, dental caries, etc. The present review focuses on the beneficial effects of tea consumption on human health.

Keywords: Antioxidants, Theaflavonoides, Anticaries, Ethanol intoxication, Tea consumption.

INTRODUCTION

Tea is one of the most consumed beverages of the world. Presently, it is cultivated in at least 30 countries around the world. Tea beverage is an infusion of the dried leaves of Camellia sinensis, a member of Theaceae family. It is an evergreen shrub or tree that can grow to a height of 30 feet, but is usually clipped to a height of 2.5 feet in cultivation. The tree or shrub is heavily branched with dark-green, hairy, oblong, ovate leaves cultivated and preferentially picked as young shoots. Older leaves are considered to be inferior in quality. Freshly harvested tea leaf is processed differently in different parts of the world to give oolong tea (2%), green tea (20%) or black tea (78%)\(^1\). Green tea is prepared from the fresh tea leaf and widely consumed in Japan and China. Western cultures favour black tea which is prepared through the oxidation, curing process of maceration and exposure to atmospheric oxygen\(^2,3\). The consumption of oolong tea is mostly confined to China and Taiwan, and roasted tea is consumed mostly in Japan. Green and roasted teas are steamed, respectively, to avoid enzymatic oxidation; oolong tea is semi-fermented to permit a moderate level of enzymatic oxidation during processing\(^2,4,5\). Also, Ilex paraguayensis is a species of tea from South America. This plant is processed to obtain a final commercial product named yerba mate. The mate is a famous popular tea consumed in Argentina, Brazil, Uruguay, and Paraguay. Even though the therapeutic properties of yerba mate have been extensively explored, there are few studies of chemical composition of mate\(^2,6,7\).

‘Healthy Foods’ containing active scavengers of free radicals are very popular nowadays. Advertisements in newspapers and magazines regarding a “Wonder Cure” that prevent damage to the body are becoming ubiquitous. It is widely accepted that phenolic compounds contained in certain foods have potential health benefits. Tea is linked to beneficial effects on human health with the polyphenols as the responsible constituents\(^8,9\).

Tea leaves as well as the resulting beverage tea are known to possess high amounts of polyphenols, especially flavanols, the so called catechins\(^5,10\). Many in vitro and in vivo effects of tea polyphenols have been reported\(^11,12,13\) including antioxidant, anticarcinogenic and hypolipidemic properties.

Chemical composition of tea

In making green tea, the tea leaves are heated to inactivate the enzymes and dried. Thus the constituents of the tea leaves are preserved in the dried tea leaves. When the tea leaves are brewed, for example 2.5 g in 250 ml of hot water for 3 minutes, about 30% of the solid materials are extracted into water. The spray-dried powder of the water extract, known as green tea solids, has been used for animal experiments. All teas are rich in polyphenolic compounds which are also present in red wine, fruit and vegetables\(^14\). Fresh tea leaf is rich in water soluble polyphenols, particularly flavanols, flavanol gallate and flavanol glycosides\(^2,15,16\). The major tea catechins: \(\alpha\)-epigallocatechin-3-gallate (EGCG), \(\alpha\)-epigallocatechin (EGC), \(\alpha\)-epicatechin-3-gallate (ECG), \(\alpha\)-epicatechin (EC), \(\alpha\)-epicatechin-3-gallate (ECG), \(\alpha\)-epicatechin (EC), \(\alpha\)-gallocatechin and \(\beta\)-catechin; constitutes 30% to 42% of the green tea solids by weight\(^17\). Caffeine accounts for 3% to 6%. The composition varies with the cultivation conditions and subsequent processing of the tea. Black tea (‘Black’ used in this context relates solely to the method of leaf processing and not to the optional addition of milk to the beverage before consumption) is produced from fresh green leaf by ‘enzymatic browning processes (driven by polyphenol oxidase) and coupled chemical oxidation of the flavanols and flavanol gallates and, to lesser extent, the flavanol (especially myricetin) glycosides and the non-flavanoid theagallin. These transformations produce a unique range of pigments including the brownish thearubigins and the red-orange theaflavins, theaflavic acids and theaflavins, as reviewed by Harbowy and Balentine\(^18\). The thearubigins are the major polyphenols of black tea leaf and beverage. Their content has been variously estimated as 3-6%. In this process, commonly referred to as fermentation, the caffeine content in the tea leaves is not significantly changed.
Theaflavins contribute to the taste, the bright red orange colour of black tea, and account for 2% to 6% of the dry weight of black tea extracts. The major theaflavins are theaflavin-3-digallate, theaflavin-30-gallate and theaflavin-3, 30-digallate. Black tea contains greater proportion of the complex catechins such as epigallocatechin gallate and other phenols such as theaflavins and the rubigins generated by the oxidation processes used in tea production. Dall Orto et al reported the presence of flavonoids and phenolic compounds (p-coumeric and ferulic acid) in about 10% of dry weight in yerba mate.

Tea with antioxidant property
In human body, different protection mechanisms are present to combat free radicals. Also, there is equilibrium between pro-oxidative and anti-oxidant process, and when this equilibrium is disturbed in favour of free radicals, oxidation stress results. The oxidation of lipoproteins plays an important role in the development of atherosclerosis by means of oxidation process, low density lipoproteins (LDL) of vascular walls. LDLs are very rich in cholesterol causing change in structure of vascular walls. These structural modifications encourage macrophages to pick up the oxidized LDL, promoting a change into foam cells. A collection of these cells in the vascular walls leads to the first noticeable change of the artery, which could cause angina or vascular occlusion. It is well established that other pathological states such as cancer, rheumatoid arthritis, ischaemic reoxygenation injury of the liver and other organs, are set of by oxidation processes.

The powerful antioxidant properties of the tea are generally attributed to its flavonoid components; theaflavins, bisflavanols and theaflavic acids. These compounds are all potent antioxidant in vitro and, when consumed, may act as the free radical scavengers which remove endogenously generated superoxide, peroxyl and hydroxyl radicals. The antioxidant property of tea is also associated with several other mechanisms e.g. depolarization of electrons, formation of intramolecular hydrogen bonds rearrangement of the molecular structure. These compounds may also prevent oxidative reactions by chelating free copper and iron, which may catalyze the formation of reactive oxygen species in vitro.

The antioxidant flavanoids appear to be readily taken up by the human gastrointestinal tract. Van het Hoff et al have demonstrated that tea catechins, from both green and black teas, appear in human plasma and in circulating lipoprotein fractions. Five cups of tea consumed at 2-hours intervals was sufficient to elevate plasma catechin concentrations by up to 12-fold in a UK based study. The consumption of black tea with milk did not impair the bioavailability of the tea catechins. Maxwell and Thrope reported that tea consumption had no effect on total plasma antioxidant status. Conversely, Serafini et al reported that green and black teas significantly elevated plasma antioxidant potential, as measured using a fluorescence assay. Beverage tea, rich in antioxidant polyphenols, affects host biochemistry and carcinogenesis at important target organs such as colon or mammary glands in rats. This depletion of antioxidant power is observed with soya milk as well as cow’s milk and in less marked with skimmed and semi-skimmed milks. It suggests that the depletion of antioxidant effect is due to associations between the tea flavanoids and milk fat rather than proteins.

Tea with anticancer property
Many epidemiological, case-control, and cohort studies have been conducted to investigate the effects of tea consumption on human cancer incidence, and this topic has been reviewed by several authors. In a Japanese cohort study, a negative association was found between green tea consumption and total cancer incidence, especially among females drinking more than 10 cups per day. The effect of tea on stomach cancer has been the most extensively studied. Of 15 studies, five case-control studies showed a protective effect of tea on the risk of stomach cancer. Several studies have been done on tea drinking and colorectal cancer, with inconclusive or no
evidence of an association. A recent study on middle-aged Finnish men indicated a positive association between increased green tea consumption and colon cancer risk\textsuperscript{43}. However, the results with green tea showed a protective effect of tea\textsuperscript{36,37}. A large study of pancreatic, colon, and rectal cancers indicated decreased incidents of these cancers with consumption of tea\textsuperscript{36}. The results from the epidemiological studies regarding tea intake and lung cancer are unclear because smoking factor was not taken into account in the study design. There is also some evidence that green tea polyphenols have a chemopreventive effect against cancers in smokers\textsuperscript{45}. The frequency of sister-chromatid exchange in lung cells was lower in smokers who consumed green tea. In a seven-year follow-up study of patients with breast cancer, it was found that increased consumption of green tea was associated with decreased numbers of axillary lymph node metastases especially among premenopausal patients with stage I and II breast cancers\textsuperscript{46}. Early studies have linked tea drinking to both increased and decreased risks of esophageal cancers, but recent studies have shown that the positive association between tea and esophageal cancer was because of the high temperature at which the tea is consumed. Findings from the largest study of esophageal cancer conducted in China suggested that, barring the effect of temperature, drinking green tea decreases the risk of esophageal cancer\textsuperscript{47}. The anti-carcinogenic activities of tea polyphenols are generally believed to be related to their antioxidative properties. Tea may affect the metabolism of carcinogens by induction or inhibition of various cytochrome P\textsuperscript{450}s, but the practical importance of this mechanism is not known. Among the phase II enzymes, tea increases glucuronyl transferase activity, which may facilitate the detoxification pathway of certain carcinogens. Inhibition of tumor promotion-related enzymes, such as lipoxygenase and cyclooxygenase\textsuperscript{48,49}, ornithine decarboxylase\textsuperscript{50,51,52}, protein kinase C\textsuperscript{52,53,54}, and 5α steroid reductase isoenzymes\textsuperscript{55} has been shown. The antiproliferative effect of tea polyphenols has been demonstrated at both the initiation stage\textsuperscript{55} and the progression stage\textsuperscript{55} of lung tumorogenesis. In cell lines, EGCG and other tea catechins have been shown to inhibit cell growth and transformation. Some of these activities are believed to be attributable to the inhibition of MAP-kinases and AP-1 activities\textsuperscript{56,57}. Fujiki et al\textsuperscript{58} demonstrated that EGCG and other tea polyphenols inhibit growth of human lung cancer cells with a G2/M phase arrest of the cell cycle. The involvement of the tumor necrosis factor α pathway in the inhibition process has been suggested. EGCG and other tea polyphenols have been shown to inhibit the phosphorylation of Rb by Cdk2/4\textsuperscript{59} and the binding of epidermal growth factor and TPA to their respective receptors and thus inhibit tumor promotion\textsuperscript{58,60}. Green tea polyphenols also enhance apoptosis, and this has been shown in many cancer cell lines such as PC-9, H661, KATO III, DU145, A431, LY-R, HaCaT, W138, and Molt-4\textsuperscript{61}. This study suggests that a prooxidative mechanism may be involved\textsuperscript{62}. EGCG has also been shown to inhibit angiogenesis by inhibiting the growth of endothelial cells whereas green tea reduced significantly vascular endothelial growth factor-induced corneal neovascularization\textsuperscript{63}.

**Green tea and ethanol intoxication**

The defense against long-term ethanol exposure is provided by both endogenously synthesised and exogenous antioxidants. The latter are derived from beverages and diet. The therapeutic effect of green tea is associated with its catechins. Catechins are polyphenols with two hydroxyl groups in the B ring of the catechin molecule. These compounds possess the ability of preventing the formation of oxygen radicals, by inhibiting the activity of the enzymes involved in their generation. The liver is the richest source of xanthine oxidase, especially during ethanol metabolism\textsuperscript{64}. Green tea extract inhibits the activity of xanthine oxidase \textit{in vitro}, thus inhibiting superoxide anion generation\textsuperscript{65}. Long-term ethanol exposure leads to an increase in the concentration of free ferrous ions which catalyze the Haber-Weiss reaction and hydroxyl radical generation and in result to an increase in lipid peroxidation. Catechins may diminish pro-oxidative action of transition metal ions by chelate formation. It is suggested that catechins can serve as scavengers of aqueous peroxyl.
radicals near the membrane surface while α-tocopherol within the membrane.

**Anticaries effect of tea**

With respect to the effect of tea extracts on dental caries, Oolong tea extract (OTE) has been reported to contain substances, notably polyphenols, that have antibacterial properties against oral pathogens, such as *Streptococcus mutans*, the bacteria closely associated with dental caries. Some studies suggested that a diet supplemented with green tea may beneficial in dental caries management. Lingström et al. found that frequent mouth rinsing with black tea infusion may contribute to oral health by inhibition of plaque, its acidity and its cariogenic microflora. Green tea and coffee contain varying amounts of fluoride. Cariostatic properties of fluoride in water supply, dentifrices and topical gels have been documented. However, most of the reports suggest that the anti-caries effect observed with green tea is due primarily to the antibacterial properties of the organic components (polyphenols, tannins) rather than the cariostatic effect of fluoride.

High fluid intake, including tea intake, is generally considered the most effective and economical means of preventing kidney stones. However, tea consumption has been found to increase urinary oxalate levels in healthy individuals, and some experts continue to advise those prone to calcium oxalate stone formation to limit tea consumption.

**CONCLUSION**

Most of the effects of tea are associated with flavonoids and their antioxidant potential. These manifest counter acting power of body towards naturally generated or externally invaded oxidizing species. The polyphenols present in tea can also decrease the risk factor of specific type of cancers by inducing phase I and phase II metabolic enzymes that increase the formation and excretion of detoxified metabolites of carcinogens. The research interest based on tea components may provide an approach to decrease the incidence of and mortality from various diseases. Overall tea is an affordable beverage of natural origin compared to modern beverages such as soft drinks.
