Abstract

Purpose: To investigate the effect of α-keto acid tablets, and risk factors for cardiovascular calcification in patients with chronic kidney disease (CKD).

Methods: A total of 128 CKD patients were enrolled in this study. They were randomly assigned to study and control groups, each with 64 patients. Control patients received symptomatic treatment, while the study group patients received α-keto acid tablets plus. Indices of cardiovascular calcification, blood lipids and mineral metabolism were determined in the 2 groups of patients and compared. Risk factors for cardiovascular calcification were also analyzed.

Results: After treatment, the two groups had decreased CACS scores and reduced serum FGF-23 levels, with lower values in patients in the study group. Levels of Klotho and fetuin-A were significantly elevated after treatment, with higher values observed in study group patients. The degree of cardiovascular calcification was markedly lower in study group than that in controls. There was no significant difference in blood Ca level between the control and study groups before and after treatment.

Logistic multivariate analysis demonstrated that hyperlipidemia, hyperphosphatemia, hypercalcemia, hypertension and diabetes put patients at risk for cardiovascular calcification.

Conclusion: Compound α-keto acid tablets delay cardiovascular calcification in patients with CKD, and alleviate symptoms of related risk factors for cardiovascular calcification.

Keywords: Compound α-ketoacid tablets, Chronic kidney disease, Cardiovascular calcification, Risk factors

INTRODUCTION

Chronic kidney disease (CKD) is one of the most common chronic ailments at present, with a prevalence of about 5 – 10 %, and it is associated with heavy burden on global public health resources [1,2]. Cardiovascular calcification is a common complication in patients with CKD, and it may be fatal for patients with terminal-stage renal ailment [3]. A prospective study on 110 maintenance hemodialysis patients with cardiovascular risk showed that each 1-point increase in carotid calcification score resulted in a 2.6-fold increase in death risk [4].

Nonetheless, there is no effective treatment for cardiovascular calcification in patients with CKD.
Conventional treatment is applied using low protein diet to prevent and treat kidney damage caused by proteins [5]. Cardiovascular calcification in CKD patients is attributed to disorders in mineral metabolism. Studies have demonstrated that α-keto acid tablets are calcium salts which regulate disorders in calcium and phosphorus metabolism in patients [6,7]. However, there are no studies on the suppressive effect of compound α-keto acid tablets on cardiovascular calcification process in patients with CKD.

Therefore, this study was carried out to provide effective treatment guide for cardiovascular calcification in patients with CKD through investigation of the effect of compound α-keto acid tablets on cardiovascular calcification process in these patients.

METHODS

Patients

A total of 128 patients with CKD were recruited from July 2016 to March 2019, as research subjects. The diagnosis of CKD was based on National Kidney Foundation/ Kidney Disease Outcome Quality Initiative (NKFK/DOQI) classification standard [8]. Glomerular filtration rate (eGFR) was measured as stipulated in Modification of Diet in Renal Disease (MDRD). The patients comprised 73 males and 55 females, and they were assigned to study and control groups (n = 64 each).

Patients with acute infection or trauma, those with severe cardiovascular and cerebrovascular diseases, malignant tumors or blood diseases; and patients with obvious mental disorders were excluded from the study. All patients signed informed consent form. The study was approved by the institutional ethics committee of Affiliated Hospital of Guizhou Medical University, Guizhou, China (approval no. = GZ15038864). The protocol used in the study was in line with the guidelines for human studies in the Declaration of Helsinki [9].

Treatments

All patients were given low-phosphorus and low-protein diet. Erythropoietin was administered via subcutaneous injection at a dose of 10,000 U/day. Folic acid was given at an oral dose of 5 mg thrice daily. Iron was administered to all patients to maintain hemoglobin (Hb) at normal level, and to correct anemia and acidosis. Symptomatic treatments such as blood pressure control and blood sugar control were administered according to the patients’ conditions. Moreover, the study group was treated with compound α-keto tablets which were given orally three times a day. Patients in both groups were observed for 6 months.

Measurement of cardiovascular calcification

Imaging: 64-slice spiral CT was used for plain scanning of the coronary artery. A slice of thickness 5 mm, CT peak >130H, and calcification area ≥1 mm² was adjudged as positive indication of coronary artery calcification. Coronary artery calcification score (CACS) was calculated as indicated in Eq 1.

\[
\text{CACS} = \text{CTpc} \times \text{CA} \quad \ldots \ldots \ldots \ldots \text{(1)}
\]

where CTpc is CT peak coefficient, and CA is calcification area.

Determination of serum cardiovascular calcification index

The levels of fibroblast growth factor (FGF-23), Fetuin-A and Klotho were determined using their respective enzyme-linked immunsorbent assay (ELISA) kits.

Determination of lipid metabolism indices

Sera from fasting venous blood were subjected to assay of levels of triglycerides (TGs) and total cholesterol (TC) using an automatic Biochemical Analyzer (Thermo Scientific™ Indiko™).

Determination of mineral metabolism index

Blood levels of calcium (Ca) and phosphorus (P) were determined in fasted venous blood using an automatic Biochemical Analyzer, and the calcium-phosphorus product \((\text{Ca} \times \text{P})\) was calculated.

Statistical analysis

The data obtained in the study were analyzed using SPSS version 19.0 software. Measurement data are presented as mean ± standard deviation (SD), and were compared between the two groups using Student's t-test. Paired t-test was used for comparison of data before and after treatment. Counting data are presented as number and percentage \([n, (\%)]\), and were analyzed using chi-squared \((\chi^2)\) test. Logistic regression model was used to analyze risk factors for secondary cardiovascular calcification. Values of \(p < 0.05\) were taken as indicative of statistically significant differences.
RESULTS

Clinical profiles of patients

There were no significant differences in gender, age, BMI and CKD types between the control and study groups ($p > 0.05$).

Indices of cardiovascular calcification

After treatment, patients in the two groups had decreased CACS scores and reduced serum FGF-23 levels, with lower values in study group patients. The levels of Klotho and fetuin-A were significantly elevated after treatment, with higher values in study group. After 6 months of treatment, 21 study group patients had cardiovascular calcification, accounting for an incidence of 32.81%. There were 38 patients cardiovascular calcification in the control group, accounting for an incidence of 59.37%. The incidence of cardiovascular calcification was markedly lower in the study group than in controls.

Mineral metabolism indices

After treatment, blood levels of P and calcium-phosphorus product (Ca × P) in both groups were markedly decreased, and their values were markedly lower in study group patients than in controls. There were no significant changes in the blood levels Ca in both groups (p > 0.05). These results are shown in Figure 3.

Figure 3: Effect of treatments on mineral metabolism indexes in the two groups. *P < 0.05

Univariate analysis of secondary cardiovascular calcification in the patients

Patients with vascular calcification (n = 59) and non-vascular calcification patients (n = 69) were analyzed. Single factor analysis showed no significant differences in terms of gender and age between both groups (p > 0.05). In contrast, the application of compound α ketoacid tablets resulted in significant differences in incidents of hyperphosphatemia, hypercalcemia, hypertension and diabetes (p < 0.05; Table 2).

Multivariate analysis of factors likely to have negative impacts on patients having hypothyroidism and cardiac insufficiency

Patients with hyperlipidemia, hyperphosphatemia, hypercalcemia, hypertension and diabetes were analyzed, with cardiovascular calcification as dependent variable. Results of logistic regression analysis showed that hyperlipidemia, hyperphosphatemia, hypercalcemia, hypertension and diabetes constituted independent predisposing factors for cardiovascular calcification.

DISCUSSION

Vascular calcification constitutes a serious threat to the cardiovascular health of patients with kidney disease [10]. Therefore, the risk factors associated with the development of cardiovascular calcification were analyzed in the present study, with a view to providing data which will contribute to the prevention of cardiovascular calcification and reduction in deaths due to cardiovascular disease in CKD patients.

Compound α-keto acid tablet, a compound preparation containing 5 amino acids, 4 keto amino acids (calcium salts), and 1 hydroxy amino acid (calcium salt), provides essential amino acids for patients with CKD through amination or transamination [11]. Moreover, compound α-keto acid tablets produces essential amino acids by interacting with urea nitrogen; it inhibits protein catabolism, and increases the level of amino acid metabolism and metabolic acidosis in vivo [12, 13]. In addition, the calcium component of compound α-keto acid tablets combines with phosphorus in vivo and reduces blood phosphorus levels, thereby improving the metabolism of calcium and phosphorus in patients [14].

In this study, it was found that treatment with compound α-keto acid tablets resulted in marked lowering of blood levels of P and Ca × P in patients in the study group, when compared with patients in the control group, as well as effective improvement in blood lipid levels of patients, although there were no significant changes in blood Ca levels. A previous study [15] found that calcium salt of keto acid combined with phosphorus in intestinal tract, thereby reducing the absorption of phosphorus. Moreover, the application of compound α-keto acid preparation reduced the intake of sulfur and phosphorus amino groups, thereby leading to correction of metabolic acidosis [15]. This also explains how compound α-keto acid tablets reduce the level of P in blood.

Through serum assays and CT examination, it was found that CACS score and serum FGF-23 level were significantly reduced in both groups after treatment, with lower values in the study group. In contrast, the levels of Klotho and Fetuin-A were elevated in the two groups after treatment, with higher levels of Klotho and Fetuin-A obtained in study group patients. Osteoblasts secrete FGF-23, a regulator of calcium and phosphorus metabolism. It influences calcium and phosphorus metabolism by binding to the receptor of Klotho. As the disease advances, FGF-23 resistance and Klotho receptor may decrease, resulting in progressive increases in FGF-23 levels [16]. Klotho receptor inhibits calcification independent of FGF-23, a property which makes it useful as an endogenous inhibitor of vascular calcification [17]. Fetuin-A is a vascular calcification inhibitor which competitively combines with circulating Ca and P, thereby suppressing their deposition in pathological mineralized tissues, mineralized bone matrix and atherosclerotic plaques [18]. The results obtained in this study suggest that compound α-keto acid tablets may effectively delay cardiovascular calcification through a mechanism involving down-regulation of the expression of FGF-23 expression and up-regulation of the expressions of Klotho and fetuin-a.

Furthermore, results from risk factors analysis for cardiovascular calcification revealed that
hyperlipidemia, hyperphosphatemia, hypercalce-
mia, hypertension, and diabetes constituted
independent predisposing conditions for
cardiovascular calcification in CKD patients. A
previous research revealed that lipid deposition
on the vascular wall is one of the important
material bases for cardiovascular calcification
[19]. Moreover, it has been reported that hyperphosphatemia and
hypercalcemia were risk factors for
cardiovascular calcification [21]. The results of
the present study suggest that compound α-keto
acid contributes to mitigation of
hyperphosphatemia in CKD patients.

Limitations of the study
The sample size used in this study was small.
Moreover, the follow-up time was short.
Therefore, there is need for further clinical
studies to validate the findings reported here.

CONCLUSION
Compound α-keto acid tablets delays
cardiovascular calcification in CKD patients and
alleviates symptoms of related risk factors for
cardiovascular calcification.
